CURRENT PROCEDURE IN MANAGEMENT OF OBSTRUCTION OF SMALL INTESTINE

Clarence Dennis, M.D., Pelham Manor, N. Y.

The mortality associated with acute obstruction of the jejunum or ileum has progressively improved since the 40% figures seen before Wangenstein's introduction of nasal suction siphonage. The most recent available figures suggest a mortality rate of about 11%.¹ Although the occurrence of ileac obstruction is therefore not as catastrophic now as it formerly was, it still commands a very real risk and is worthy of most thorough consideration.

Failure of the small intestine to transport and handle material normally may be due either to actual mechanical obstruction to the lumen thereof or to paresis of the musculature of the intestine. The latter condition is seen in inflammatory reaction surrounding the involved segment or occurs reflexly in association with such conditions as renal colic or retroperitoneal hematoma. It is with mechanical complete acute obstruction that this paper is concerned.

The anatomical factors underlying such obstruction, in the approximate order of frequency, are: (1) external hernias, (2) adhesions and adhesive bands, (3) intussusception, (4) gallstone obstruction, (5) volvulus, (6) internal hernias, and (7) neoplasms. This list does not include neoplasms that have disseminated throughout the peritoneal cavity, engaging the small intestine sufficiently to produce obstruction.

PATHOLOGICAL FEATURES

Pain.—There is no sensation of pain from the wall of the intestine upon crushing (unless nerve trunks are involved), or upon cutting or burning, but it is highly sensitive to stretching. When obstruction occurs, the peristaltic activity of the intestine above it brings fluid and gas in quantity to produce distention first of the area just above the block but ultimately all the way to the duodenum. It is the stretch due to this distention that is responsible for the typical pain of small intestine obstruction. There is support for the thesis that the waves of propulsive activity in the intestine come with somewhat greater fre-

quency high in the ileum than lower down. In practice, an obstruction high in the ileum appears to be characterized oftener by a period of three to five minutes between peaks of crampy pain, and obstruction in the terminal ileum intervals between the pains that are as much as twice as long.

Tension on the root of the mesentery produces diffuse pain, which is noted maximally across the abdomen in some cases and maximally across the back in others. Rapidly developing edema or hemorrhage into the mesentery or retroperitoneally appears in some cases to be the only tenable explanation of back pain. Incomplete disappearance of pain in the abdomen between the cramps of ileac obstruction may be due, therefore, to rapid distention or to tension on or rapid swelling of the mesentery, which is seen especially in strangulating intestinal obstructions.

Borborygmus.—The term "borborygmus" means any intestinal sound due to flatus whether it is produced in normal or in abnormal circumstances. In the presence of supraobstruction, the stretch on the ileac wall is associated with a pitch of sound that is higher as the degree of tension is increased. In general, sounds above high C (512 vibrations per second) are heard in clinically developed obstruction of the ileum. Under this circumstance, a listener usually hears with his stethoscope a rush of splashing, gurgling sounds that start at a low pitch but in the course of half a minute or so rise to the high-pitched "tinkles" described. Arrival of a wave of peristaltic activity at the supraobstruction site of distention determines therefore both the peak of pain and the high-pitched borborygmi. The coexistence of these phenomena establishes the diagnosis of obstruction of the small intestine in more than 9 out of 10 cases.

Vomiting.—In the presence of small intestine obstruction, there is increased irritability of the intestine that is most distended, and retrograde peristalsis occurs with dumping of the intestinal content into the stomach, from which much of it is vomited. The import of vomiting

as a component of the picture depends primarily on the level of obstruction. The reasons for this are apparent on review of the estimated volumes of fluid that pass a given point per day, as shown in the table.

An obstruction high in the ileum will result in huge losses of water, sodium, and chloride and some loss of potassium. In adults, the over-all effect is one also of alkalosis, as usually the loss of sodium is less than that of chloride. An obstruction in the terminal ileum is associated, on the other hand, with relatively little severe privation of fluid and salts, for most of the upper intestinal secretions are reabsorbed, at least in the first few days.

In patients, as in dogs experimentally, the vomitus begins to assume a fecal character in $3\frac{1}{2}$ to 4 days after complete obstruction is established.² This is related to the length of time the material remains in the presence of the bacterial activity of the intestine, and is virtually unrelated to the level in the intestine at which the block has been established. An example is the fecal vomiting seen in obstruction of the distal loop in poorly patterned gastroenterostomy.

Dehydration.—From what has been noted above, it is apparent that dehydration is slow to develop in terminal ileac obstruction. It may be overwhelming, however, in two to three days in high ileac or jejunal obstruction.

Daily Volumes of Fluid That Normally Pass Several Levels of the Intestine

Level of Intestine	Vol. of Fluid
Duodenojejunal junction (ingested fluid, secretions of salivary, gastric, and duodenal glands, and of liver and pancreas)	8-10 liters
Middleum	8-10 liters ?
Ileocecal junction	0.5 liter

Distention.—Clinical distention as a consequence of obstruction is apparent in relation to the sum total of increased visceral volume. The jejunal obstruction is associated with distention of a short segment of intestine, and clinical abdominal distention is not marked. As one considers cases with blocks at progressively lower levels in the ileum, the length of intestine involved in distention is progressively greater and the degree of abdominal distention is usually progressively more pronounced.

Roentgen Findings.—The roentgen findings on flat and upright scout films of the abdomen are diagnostic in approximately five cases out of six. The ladder-like arrangement of gas-filled segments is a familiar picture. In obstruction of increasing duration, the ratio of gaseous to fluid content decreases, until there may be virtually no apparent gas at the end of seven or eight days.

Obstipation.—Failure of passage of gas or stool by rectum may not occur until one or two days after obstruction is established. Failure of return of anything more than the injected enema fluid thereafter is support for the diagnosis of obstruction.

Shock.—Depression of blood pressure, rapid, thready pulse, cold extremities, and collapse may result from withdrawal of a large share of the blood volume from the circulation. This may occur in acute strangulating obstructions involving more than one-third of the small intestine, in which the strangulating mechanism, whether a narrow hernia neck, a heavy adhesive band, or other agent, closes off the easily compressible veins before closing the more difficultly compressible arteries. As a consequence, blood is trapped in the involved segment, with hemorrhage and engorgement. When strangulation becomes established after several days of vomiting and privation, involvement of smaller segments of intestine may bring about shock, for under these circumstances there is already contraction of blood volume before strangulation takes place.

Signs of Peritoneal Irritation.—Escape of blood or of exudate into the peritoneal cavity causes sufficient reaction to produce clinical findings of parietal peritoneal irritation, such as abdominal spasm, tenderness to palpation, and rebound tenderness. Along with such localized findings, elevation of temperature and leukocytosis commonly accompany the inflammatory responses to strangulation.

CAUSES OF DEATH

The lethal factors fall naturally under three general headings: (1) salt and water imbalance, (2) strangulation and consequences thereof, and (3) prolonged distention with toxic absorption. It is apparent that the large water and salt loss of obstruction high in the small intestine must quickly lead to profound dehydration, salt loss, and alkalosis, with sunken eyes, loss of skin turgor, and dry and sticky tongue. The absence of sufficient water for adequate renal function is followed in but a few days by uremia as well. These factors are lethal if uncompensated.

The mechanisms by which strangulation may be lethal are dual. Shock, as indicated, may suffice. Gangrene may lead to perforation and peritonitis if the segment in question is in the peritoneal cavity, or to sepsis and possibly death if it is not in communication with the abdominal cavity, as in femoral hernia.

Prolonged distention has been known to alter the normal semipermeability of the intestinal mucosa since Sperling showed that a sustained tension of 15 cm. of water in the dog leads to vascular stasis and changes in the histology of the membrane,³ lowering the viability of the intestine and opening an abnormal avenue of absorption, namely, the transperitoneal route. Poth and Knotts demonstrated that the products so absorbed are chiefly of bacterial origin, for they showed that the placing of succinylsulfathiazole in closed loops in the dog prolongs survival five fold.⁴ R. M. Nelson has demonstrated that the products of the paracolon bacillus are among the factors involved and has worked out a technique of titrating the amount of the exotoxin of this organism in the blood stream of the dog in response to ischemia of the bowel wall.

PROPHYLAXIS AGAINST OBSTRUCTION

Certain definitive steps can be taken in the prevention of obstruction of the small intestine. It is obvious that external hernias, particularly femoral hernias, should be

carefully sought in routine physical examinations, and repair advised wherever obstruction is considered a possibility.

Inasmuch as postoperative adhesions are the second most important etiological agent in production of small bowel obstruction, the means to prevent them must be carefully considered. As in my experience, Nemir¹⁰ found the vast bulk of adhesive obstructions to be after-maths of operations for gynecological problems, for appendicitis, and for idiopathic ulcerative colitis. In one period of review, I found that more than half of all strangulating obstructions at the University of Minnesota Hospitals followed laparotomy for gynecological procedures.

Appendicitis with extension is notorious for production of manifestations of obstruction at the time of the acute process, but in those cases in which the policy was formerly to utilize conservative management, it was almost regularly observed that exploration for appendectomy six weeks later revealed no residual adhesions. One cannot escape the suspicion that the surgeon rather than the disease process is responsible for the late obstructive manifestations so commonly seen.

The surgical world was alerted to the dangers of talcum powder by Antopol⁵; and talc has been eliminated as a lubricant for surgeons' gloves by a large share of the hospitals in the country. Studies on adhesion formation at the University of Minnesota showed indeed that excoriation of the terminal ileum over a 12 in. (30 cm.) segment, followed by application of phenol or painting with 7% iodine solution was not productive of obstructive adhesions. Injection into the unopened abdomen of the dog of washings from two pairs of talc-treated surgeons' gloves was usually lethal, the mechanism being death from adhesion obstruction.⁶ Talcum powder has been replaced in many hospitals by a partially hydrolyzed starch preparation, which is known to be removed by the body and to cause many fewer adhesions than talc.⁷

One cannot assume, however, that hydrolyzed starch is wholly innocuous if placed in the abdomen, for the most ubiquitous adhesions in my experience were seen on re-exploration within two weeks after a laparotomy in which it was known that this agent alone had been left and only in small amount. The avoidance of deposition of any powder at all in the abdomen seems the safest prophylaxis against adhesion formation on this basis. Removal of glove powder by washing in a glove basin containing water or solution of some kind is common practice and is inadequate, for if one completes such a wash and watches as the gloves dry in room air, much of the powder may be seen still on the glove surface; especially is this true if several persons have preceded the observer in use of the powder basin. The most casual observation will convince the critical of the superiority of utilization of a wet abdominal pack for actually wiping the gloves clean, or preferably two packs in series (fig. 1). Prompt change of torn or punctured gloves during operations is obviously important from this point of view as well as from that of infection.

Additional factors in the prophylaxis of adhesions that are apparently of particular importance, especially in the early postoperative period, are the rigid avoidance

of unnecessary trauma and attention to hemostasis. Rhoads and his associates have shown that clean, sharp dissection produces far less adhesion formation than blunt dissection.⁸ Precise hemostasis is possible in most laparotomies with greater ease by the proper use of the coagulating current than by the customary clamp-and-tie technique. Reexamination of wounds in the experimental laboratory has confirmed this impression. The simplest procedure utilizes a fine-tipped hemostat such as a mosquito clamp or an Adson clamp for precise grasping of the bleeding vessel and coagulation by means of a cord clipped to the handle of the hemostat. Current is most easily controlled by the surgeon through the foot switch of the diathermy machine. Some practice is required to gain proficiency in the method and a non-explosive anesthetic agent should be employed, but the dividends are real. There has been almost no adhesive obstruction after colectomy for idiopathic ulcerative colitis in my experience since adoption of this technique eight years ago.⁹

Fig. 1.—Proper method of removing glove powder before operation. Rinsing in a wash basin is dangerous because removal of powder is incomplete. Best results follow use of two cloths.

MANAGEMENT OF ACUTE OBSTRUCTION OF SMALL INTESTINE

For many years, I was a member of Wangenstein's staff at the University of Minnesota. A concerted effort was made by that group as a whole to evaluate fully and critically the role of nonoperative management of those cases of acute complete small intestine obstruction that failed to present any of the following evidences of actual or impending strangulation: history of sudden onset

(suggested by McKittrick and Sarris¹⁰); back pain, shock, signs of peritoneal irritation, fever, leukocytosis, bloody intestinal drainage, palpation of "soggy" loops on bidigital pelvic examination¹; evidence of hernia; and obviously strangulating mechanisms such as intussusception and gallstone obstruction.² In addition, each patient was reexamined and his condition reevaluated every four to six hours during the period of conservative management, and appearance of any one of these signs removed him to the operative group. The only other indications for operation were failure to decompress the intestine by intubation and failure of the obstruction to relent after decompression had been accomplished.^{1a}

The results of concerted attention to this policy were gratifying indeed, and in the last year for which data are available to me, there were 2 deaths in 27 patients—a statistically insignificant rate of 7.4%.^{1a} The difficulties in such a pattern arise from the observation that remarkable enthusiasm on the part of highly trained and experienced personnel is absolutely essential to maintain a sufficiently informed and alert watch on these patients. They arise, in addition, from such experience as mine; in two of my personal patients, both physicians, ultimate exploration because of failure to relent revealed strangulating mechanisms. Both men recovered, but it was the consensus that their risks would have been less and their hospitalizations shorter with earlier exploration.

To support the change in point of view toward early operation, several advances have contributed to the safety of that intervention. Some of these are as follows:

(1) Smith and Brackney's rapid method of peroral intubation of the small intestine¹¹; (2) Wangenstein's

Fig. 2.—Flexible stylet with controllable tip of Smith and Brackney. After insertion of plastic tube on the stylet into the stomach, the tip can be directed to the pylorus under fluoroscopic control. (Reproduced from *Surgery* [27: 817, 1958] by permission of the publisher.)

technique of aseptic decompression of the distended intestine³; (3) my demonstration that healing of anastomotic lines in distended small intestine occurs smoothly and consistently if appropriate techniques are employed²; (4) removal of the entire block of contaminated tissue from the patient in certain types of obstruction; (5) the

antibiotics; and (6) removal of the fear of production of new adhesions by surgical intervention.

Preparation of the Patient for Exploration.—With the decision that in virtually all cases of acute complete obstruction of the small intestine exploration should be done on admission of the patient to the hospital, certain additional measures for preparation are in order.

Fig. 3.—Modified Wangenstein aseptic decompressive suction enterotomy. A, method of emptying a distended segment of small bowel preparatory to enterotomy. B, placement of a double purse string to secure the bowel to the trocar. After placement of the purse strings, a 1 cm. incision in the center exposes the intact mucosa so that easy perforation will be possible with the plunger point. C, securing of trocar. Following perforation of the mucosa, the plunger is withdrawn and the catheter is slipped into the bowel. D, suction decompression. Very gentle lifting of the segments of bowel will direct content to the catheter. The entire small bowel can be delivered and emptied by this means, particularly if a three-foot catheter is employed. E, clean removal of the trocar. F, closure of the defect. G, completion of closure. The closure process may be eliminated altogether in strangulation if a segment is employed close enough to the necrotic bowel to permit block excision of the entire area with immediate anastomosis. (Reproduced from "Operative Technic in General Surgery," edited by W. H. Cole, as modified from "Intestinal Obstructions" by Wangenstein, with permission of Charles C Thomas, Publisher.)

If frank clinical dehydration is present, it may be reasonably assumed the patient has lost water equal to from 5 to 7% of his original body weight. Since the bulk of the fluid lost is vomitus, which contains about one-half the concentration of sodium chloride in plasma, this fraction of the body weight should be given in 0.45% sodium chloride solution containing 2.5% dextrose in the first few hours, with addition of the estimated daily require-

ment the first day. One-half this amount, or 3% of the body weight can safely be given the first hour, under the circumstances, while intestinal intubation is being undertaken and the initially drawn blood is being analyzed for sodium, chloride, potassium, bicarbonate, and total protein concentrations, and the balance, or the second 3%, given during the operation and the ensuing four to six

hours, with such alterations as may be dictated by the laboratory results. Lesser degrees of dehydration may be estimated clinically and by evaluation of the chemical determinations and corrected less vigorously.

Rapid Intubation of Small Intestine.—The method of Smith for the intubation of the small intestine depends on fluoroscopic control and a flexible stylet with a controllable tip (fig. 2). In Wangenstein's clinic, Smith was able to intubate the small intestine within one hour in 90% of 180 cases, most of which were cases of intestinal obstruction. Utilization of this method usually permits the surgeon to explore the abdomen within two to four hours of admission with a major share of the distention relieved. If the abdomen is opened in the presence of a good deal of residual distention, the Smith tube can usually be advanced under the manual control of both the surgeon and the tube operator, ordinarily with complete emptying of the intestine.

Aseptic Decompression at Laparotomy.—In certain instances the degree of distention prohibits passage of even the Smith tube, and the status of the bowel on laparotomy suggests it is too tense and friable to permit manipulative introduction of the Smith tube at that juncture. Under these circumstances, or when the Smith tube is not at hand, employment of a modification of the Wangenstein aseptic decompression technique^{12a,b} upon

the most distended segment that first comes to view regularly permits complete emptying down to the point of obstruction (fig. 3). Even if an adhesive band has cut into the bowel, it can be freed without gross spillage and proper repair accomplished.

Primary Anastomosis.—I reported 10 years ago a series of experiments in which dogs subjected to low ileac obstruction were relieved after three to eight days by resection of the area of block and primary end-to-end anastomosis. There was one failure in 16 dogs, an instance in which an obvious technical error was made. There were 2 deaths among 16 resections in clinical patients suffering from strangulating obstructions, neither owing to anastomotic failure. The technique employed was dependent on such a closed oblique anastomosis that unsullied serosal surfaces were approximated by interrupted sutures (fig. 4). Microscopic studies indicated that healing was as satisfactory in intestine previously distended by obstruction as in undistended intestine.²

The coming of the antibiotics has increased the safety of this procedure, and may indeed have lessened the need for closed anastomosis in elective cases. In emergency cases in which the adequacy of intestinal antisepsis is at best equivocal, it remains to be shown that any other method can match the security of the closed technique. The method is apparently most secure as a one-layer silk approximation. The germ of the method is shown in fig. 4, but earlier articles describe the complete technique.^{12a,c}

ANTIBIOTICS

Studies of Poth and his associates have led to recognition of a whole series of agents that are effective in destruction of intestinal pathogens.⁴ Some of these, such as neomycin, are reported to sterilize a segment of intestine in 20 minutes.¹³ The survival period in experimental strangulating obstruction is markedly prolonged also by intravenous administration of some of the antibiotics, such as chlortetracycline (Aureomycin).¹⁴

Fig. 5.—Repair of femoral hernia with gangrenous bowel. A, separation of neck of sac with retention of intact fibrous ring. B, femoral hernia sac removed intact with fibrous ring of neck and contained necrotic intestine. Reconstruction of the inguinal region was straight-forward. In one of nine cases, the hernia recurred a year later. (Reproduced from *Surgery*, [22:312, 1947] by permission of the publisher.)

It is comforting to know that the period of requirement of absolute preservation of the serosa from contamination by intestinal contents has apparently passed. It is

platitudinous on the other hand to state that minimization of such contamination, and intravenous employment of chlortetracycline or oxytetracycline (Terramycin), from the time of admission to the hospital combine to make the ordeal as safe as possible.

Block Resection of Contaminated Fields.—The block resection of the intact sac and contents in gangrenous femoral hernia with utilization of primary end-to-end intestinal anastomosis has reduced the mortality in this lesion from 60% to the neighborhood of 10% (fig. 5).¹⁵ It is a technique that is applicable, though with considerable difficulty, to strangulating inguinal hernia as well.

The same principle applies to the resection of intussusceptions too difficult to reduce, in which the risk of resection is less than that of persistent efforts to achieve reduction.¹⁶ In the original series reported, there were no deaths in 10 cases of such resection, but one patient died in the year subsequent to that report.

Removal of Fear of New Adhesions.—As indicated under prophylaxis, proper management during laparotomy should minimize the risk of fresh adhesion formation secondary to exploration for intestinal obstruction.

SUMMARY

The etiological and physiological factors involved in obstruction of the small intestine must be fully appre-

ciated to permit successful management by any program of therapy. Although it has been shown possible to achieve a low mortality rate in the management of acute complete obstruction of the small intestine by non-operative means, there are still cases of strangulation that are not recognizable without exploration. When acute complete obstruction of the small intestine is not known to be associated with complete fixation by adhesions, exploration should be done in the two to four hours after hospital admission.

New developments have made risks of such early intervention small by former standards. These are the Smith-Brackney rapid method of intubation of the small intestine, Wangenstein's aseptic decompression, the methods of primary anastomosis in the face of obstruction, the removal of the entire contaminated area of tissue en bloc in certain types of strangulation, the coming of the antibiotics, and refined surgical methods for the removal of fear of production of new adhesions by surgical intervention.

ROENTGEN STUDIES IN SUPPURATIVE PNEUMONIA OF INFANTS AND CHILDREN

John A. Campbell, M.D., David C. Gastineau, M.D.

and

Frank Velios, M.D., Indianapolis

Acute suppurative pneumonias have long been recognized as a problem of major importance to the pediatrician. This type of pulmonary disease finds its greatest incidence and mortality in infants and young children. Although its over-all incidence is estimated¹ to account for less than 10% of all childhood pneumonias, it probably causes more deaths than other forms of inflammatory reaction in the lungs. In a series of cases reported by Watkins² and associates in 1948, the mortality was 57% for children of all ages and 100% for infants.

The greater morbidity of suppurative pneumonia is attributable to the overwhelming toxicity, the tendency to form pulmonary abscesses, the pleural complications, and metastatic phenomena. In spite of the effective control of pneumonic infections by antibiotics, however, a

relatively high mortality from suppurative pneumonias continues. Since the development of penicillin, the mortality rates have been reported as reduced to 33% for children and 40% for infants.³

As a corollary to this, roentgen examination of infants and children currently hospitalized for respiratory infections has shown a steady decline in the number of primary alveolar pneumonias and an increase in the proportion of patients showing the roentgenographic characteristics of suppurative pneumonia. This paper will emphasize the principal signs by which suppurative pneumonias may be recognized roentgenologically and will evaluate their specificity.

MORPHOLOGY

Morphologically, pneumonias have been classified³ as primary alveolar, when the involvement is limited to the alveolar spaces, and secondary interstitial, when the supporting structures around the bronchi and air sacs are also involved. Suppurative pneumonias are of the latter type in that the infecting organisms invade the bronchial walls, peribronchial tissues, and interstitial structures as well as the alveoli. Alveolar pneumonia disables chiefly by reducing the patient's vital capacity through consolidation. Suppurative pneumonia adds to this the suffocating effects of bronchial edema and parenchymal necrosis.

3. Diagnostic Roentgenology, Golden, R., editor, Baltimore, Williams & Wilkins Company, 1952, vol. 2.

Whether one or the other types of inflammatory reaction will occur seems to depend largely on the type and pathogenicity of the etiological agent.

PATHOLOGY

The disease occurs chiefly by bronchogenous invasion. Studies made at autopsy⁴ suggest that the infection descends from the upper respiratory passages and spreads progressively into the peripheral portions of the bronchial tree. Extension continues by the lymphatics and interstitial tissues into the pulmonary parenchyma. Neuhof and Hirshfeld⁵ stress that this extension by the bronchial pathways accounts for the peripheral location of the suppurative lesion and the segmental distribution of the process. The tendency to involve bronchopulmonary segments gives rise to characteristic cone-shaped areas of parenchymal infiltration. The base of such a cone contacts a large pleural surface, which probably explains the high frequency of empyema in these patients.

In addition, multiple small coalescing abscesses clustered about the bronchioles in the lung periphery invite the formation of bronchopleural fistulas. The resulting tension pyopneumothorax may jeopardize the infant's life. In contrast, the pulmonary lesion of hematogenous origin rarely leads to such complications. Basically, the suppurative pneumonias show two general patterns. The first is an acute fulminating disease without tissue necrosis. The second is an acute suppurative process showing diffuse or local involvement of the lung pleura.

ETIOLOGY

The suppurative pneumonias in children are so frequently caused by *Micrococcus* (*Staphylococcus*) *pyogenes* var. *aureus* that many use the term as synonymous with micrococcic (staphylococcic) pneumonia. This may be the causative organism in the majority of instances, but there are notable exceptions. First, it has been pointed out that micrococcic pneumonias occur frequently as a complication of virus infections⁶ and epidemic influenza.⁷ In one series, about 50% of patients who died of epidemic influenza showed *M. pyogenes* in the lung cultures at post mortem.⁸ Likewise, in infants debilitated by fibrocystic pancreatic disease, the suppurative pulmonary complications are usually due to *M. pyogenes*. Less frequently encountered etiological agents are various streptococci, Friedländer's bacillus, *Proteus* organisms, and pneumococci. In addition, a very similar pulmonary process may occur in the acute suppurative phase of bronchogenous tuberculosis.

DIAGNOSIS

Only the isolation of the organism in pure culture directly from the lung or pleural cavity constitutes reliable proof of etiology. Nose and throat cultures are not positive evidence of micrococcic pneumonia. The incidence of such cultures is no greater than in unrelated conditions. In fact, sterile cultures may be obtained from the empyema fluid in some patients. This lack of correlation between the routine bacteriological tests and the type of pathological condition in the lungs makes it necessary for the pediatrician to rely on the clinical and roentgen studies for a working diagnosis in most instances.

Roentgenographic Features.—Several distinctive roentgenographic features are seen during the develop-

ment of acute suppurative pneumonia. These are not present in all patients, nor do they occur in any regular sequential order. Perhaps the most consistent feature is the rapidly changing roentgen picture. A roentgenogram of the chest may show an area of homogeneous pneumonic infiltration on one day and, after a short interval, reveal a large pulmonary cavity with a fluid level. After this, a large collection of fluid in the pleural cavity may completely obscure the parenchymal changes. This picture may again change to one showing tension pneumothorax and severe mediastinal displacement. These striking changes are of considerable importance because they frequently occur in the presence of an unchanging clinical course. At times, the paradoxical roentgen observations may be confusing to the clinician. In the presence of overwhelming toxicity, the roentgenogram

Fig. 1.—Histological abnormality of pneumatocele. The cyst is lined by exudate and a thin layer of granulation tissue. The bronchiole filled with exudate is continuous with the cavity where there is a break in the continuity of the bronchiolar wall. Elsewhere in the lung there are small abscesses.

may show only mild emphysema, while during convalescence the roentgen studies may show pulmonary and pleural invasions that are out of proportion to the clinical manifestations.

Pneumatocoles.—A second characteristic roentgenographic feature of suppurative pneumonia is the appearance of one or more cyst-like hyperventilated rarefactions called pneumatocoles. According to Conway,⁹ these constitute a special form of emphysematous interstitial cavity. The pathogenesis of these pneumatocoles is suggested by the histological findings in surgical material (fig. 1). There is first a development of a peribronchial abscess that follows penetration of the bronchial wall by the invading organism. If a perforating bronchial communication occurs, the suppurative abscess is evacuated, and an air-containing cavity results in the interstitial substance of the lung. A check valve mechanism in the bronchial fistula permits rapid emphysematous inflation of this cavity. Shifting fluid levels due to purulent exudate within the cavity may appear and disappear roentgenographically during the course of the lesion.

Early in its formation, the pneumatocole may be lined with a loosely organized, rather thin layer of granulation tissue. This lining becomes progressively thinner as the cavity enlarges under tension. With further resolution

Fig. 2.—Pneumatocole in suppurative pneumonia. Classical thin-walled tension air cyst characteristic of suppurative pneumonia is seen in the right lung. There is emphysema of the remainder of the right lung.

of the inflammatory process, the classical thin-walled cyst is formed (fig. 2). The wall of these cavities will appear considerably thicker when they contain fluid. This appearance is more frequently seen early, and it is in this stage that they are mistaken for necrotic abscess. Pneumatocoles spontaneously disappear as infection subsides because of loss of the valvular mechanism in the bronchial wall with immediate reexpansion of the surrounding lung (fig. 3). This process, however, may require months.

According to Blumenthal and Neuhof,¹⁰ the sudden appearance of these cysts on the roentgenogram, which previously revealed no area of rarefaction, virtually proves the presence of micrococcic pneumonia when it occurs in an infant, and it makes the diagnosis probable when encountered in a young child. At times, pneu-

matocoles are mistaken for congenital irreversible bronchial cysts and are removed surgically. According to Caffey,¹¹ this error is unwarranted, since in his experience most cysts demonstrated roentgenologically in infants are acquired and disappear spontaneously.

Fig. 3.—Parenchymal changes in suppurative pneumonia. Multiple pneumatocoles are present in both lungs. There is also segmental emphysema.

Infiltrative Features.—The parenchymal changes seen on roentgenographs are densities of the focal, segmental, or lobar type. Various combinations of these infiltrations are the rule, and these frequently give rise to bizarre images. The tendency for the parenchymal changes to correspond to the course of bronchi, blood

Fig. 4.—Pneumatocoles seen in figure 3 completely resolved after 14 months.

vessels, and the interlobar fissures indicates the presence of multiple inflammatory occlusions in the bronchi of the second and third order. When lobar areas of density do occur, they are more frequently due to confluent atelectasis than to pure consolidation. Because of the

bronchogenous spread, different roentgenologic stages of involvement are seen simultaneously, with changes disappearing in one lobe while they are developing in another.

The acute abscesses of suppurative pneumonia are tiny and multiple. When bronchial fistulas occur, they are converted into pneumatoceles. Otherwise, they are manifest roentgenologically as solid confluent densities

Fig. 5.—Tension pyopneumothorax in suppurative pneumonia. Sudden pleuropulmonary perforation gives this most characteristic roentgen picture in infants. The distended tension cavity displaces the mediastinum sharply to the left. The right lung is collapsed, but a pneumatocele is visible in the right cardiophrenic angle. There is an empyema fluid level across the right base.

rather than cavities. Typical chronic lung abscess rarely develops.

Pneumothorax.—As pointed out by Forbes,¹² the occurrence of a nontraumatic pneumothorax in an infant should immediately suggest the presence of an underlying micrococcic pneumonia. It is attributed to rupture of a tiny subpleural abscess or pneumatocele in check valve communication with a smaller bronchus. This type of bronchopleural fistula results in the development of empyema with alarming degrees of tension pneumothorax (fig. 5). It is more commonly observed in early infancy.

Small degrees of pneumothorax may be found early in the course of empyema formation in many infants if searched for on expiration films. The roentgen detection of such a perforating pleuropulmonary lesion should signify primary suppurative lung disease until proved otherwise. Similar results occur in cases of fibrocystic and xanthomatous infiltration of the lung, but here too, there is generally a complicating secondary suppuration.

Pleuritis and Empyema.—Pleural complications are of two types: diffuse and localized. The diffuse form develops in rapidly progressing suppuration. Tension pyopneumothorax takes place before adhesive pleuritis forms. If localized suppuration develops, however, the pleural disease is confined to the area of consolidation. A suppurative pleuritis ensues, with gradual formation

of pleural adhesions. The resultant empyema or pyopneumothorax is encapsulated. It is important not to mistake the encapsulated tension pleural cavities for pneumatoceles, since the former may require surgical management. It has been estimated by Forbes¹² that over 90% of infants under 6 months of age in whom empyema develops had micrococcic pneumonias.

Emphysema.—Segmental or diffuse forms of alveolar emphysema are a common feature of all bronchogenous suppurative infections because of the intramural bronchial edema. Interstitial emphysema is not usually seen except as it follows bronchial perforation in the formation of pneumatoceles. The segmental emphysema accompanies the inflammatory bronchial occlusions and is seen along with roentgenographic evidence of atelectasis and exudative reaction.

Diffuse obstructive emphysematous manifestations are most striking during the early stages of an acute diffuse suppuration (fig. 6). This is the fulminating variety and is rapidly fatal unless the patient responds well to antibiotics. The pathological process is widespread, with involvement of many scattered bronchopulmonary segments. There is overwhelming toxicity, and a necrotizing tracheobronchitis causes a diffuse emphysema of such magnitude as to obscure the infiltration in the lungs. Suppuration is present, but the toxemia terminates the illness

Fig. 6.—Diffuse obstructive emphysema in suppurative pneumonia. There is marked obstructive emphysema with a greater degree of involvement in the right lung. The underlying bronchopneumonia changes are obscured by the severe emphysema. Micrococcus pyogenes var. aureus was cultured from the lungs at autopsy.

before pleural invasion occurs. The paradoxical observations of clear lung fields (often interpreted as normal) in a dyspneic infant with clinical signs of severe bronchopneumonia spell an ominous prognosis to the pediatrician.

STATISTICAL ANALYSIS

An attempt was made to correlate the roentgenographic features with laboratory proof of etiology. In 85 cases reviewed for this purpose, 20 were excluded because no roentgen examination was available and 25 were not included because the laboratory confirmation was incomplete. Forty patients in whom pyogenic organisms were cultured from autopsy material, empyema fluid, and multiple blood samples had roentgen examinations. Twenty-nine of these showed roentgen changes characteristic of suppurative pneumonia. In these 29 there were 11 instances of rapidly changing roentgen picture, 15 of pneumatocele, 7 of nontraumatic pneumothorax, 16 of pleuritis or empyema, and 10 of emphysema. These specific findings occurred in addition to infiltrative changes. Of 14 cases proved by autopsy, 9 were diagnosed according to these roentgenographic changes as suppurative pneumonia.

We have found nose and throat cultures for micrococci positive in over 85% of all pediatric admissions. This criterion of diagnosis for micrococcic pneumonia is therefore unreliable. It would seem that micrococci most frequently become pathogenic when the infant's resistance is lowered by other disease or constitutional factors.

SUMMARY AND CONCLUSIONS

An unequivocal diagnosis of suppurative bronchopneumonia is probably never justified on roentgen examination alone. Nevertheless, in most instances the roentgen studies show a sufficiently high order of specificity to

provide an early recognition of this type of disease. Roentgenograms taken at judiciously spaced intervals serve as an invaluable guide for therapy by disclosing the type and extent of the pleuropulmonary complications.

There is no useful correlation between the nose and throat cultures and the etiology of the lung disease. Positive identification of the infecting organism can be achieved only by culture from the lung or pleural cavity. For this reason, roentgen examination becomes the simplest and most practical means of establishing a working diagnosis.

In an infant or younger child, certain roentgen observations closely approach pathognomonic significance. The most reliable is the occurrence of a nontraumatic tension pneumothorax. With few exceptions, pulmonary pneumatoceles are the result of interstitial suppurative invasion of the lung. A combination of diffuse emphysema, rapidly changing parenchymal signs, and diffuse or loculated empyema signify the presence of suppurative pneumonia in the great majority of instances. Although these results of roentgen studies do not specify the type of infecting organism, they are usually caused by *M. aureus* occurring at times as a complication of virus or influenzal infection. Proper utilization of roentgen examination will help to obviate the high infant mortality incident to suppurative pneumonias by supplying the pediatrician with an earlier diagnosis and more specific indications for surgical intervention.

ARTERIOGRAPHY AND VASCULAR STUDIES IN PAGET'S DISEASE OF BONE

Kenneth A. Storsteen, M.D.

and

Joseph M. Janes, M.D., Rochester, Minn.

Arteriovenous fistulas may be present in Paget's disease of bone; the question remains whether they are the primary cause of this disease or merely secondary manifestations. We have done special studies of three patients who had osteitis deformans. In the first patient, arteriograms of the involved lower extremity were done. In the second patient, both arteriograms and special vascular studies, including determination of femoral venous pressure, studies of circulation with Evans blue (T-1824), and simultaneous measurement of the oxygen content of blood in both femoral veins, were done. Only the special vascular studies were done in the third patient.

Fellow in Surgery, Mayo Foundation (Dr. Storsteen), and from the Section of Orthopedic Surgery, Mayo Clinic (Dr. Janes).

J.: The Mechanism and Incidence of Cardiovascular Changes in Paget's Disease (Osteitis Deformans): A Critical Review of the Literature with Case Studies, *Circulation* **6**: 711-726 (Nov.) 1952.

The literature contains few reports of arteriograms in extremities of patients who had osteitis deformans. Reboul¹ mentioned such a case, however, in which the lower extremity was involved. He stated, "One notices the considerable development of vascularity. All the arteries have a very large caliber. The collaterals are numerous."

We could find no records in the literature of the venous pressure, circulation time, or venous oxygen saturation of the involved extremity in Paget's disease of bone. However, several authors have demonstrated in detail an increased cardiac output and increased blood flow in bones in widespread osteitis deformans. The increased demand on the heart produces a decrease in cardiac reserve, and this predisposes to cardiac enlargement and failure.²

REPORT OF CASES

CASE 1.—A 58-year-old white man, a truck driver, came to the Mayo Clinic in May, 1950, complaining of painless swelling of the left lower leg of three years' duration. No history of trauma was apparent. The mass increased in size when the leg was dependent and receded when the patient was recumbent. It had displayed little increase in size since its initial appearance. The patient had sustained a fracture of

the neck of the right femur in 1940. He was not told that this was of a pathological type; treatment consisted of application of a cast for four months.

The patient stood with the trunk bent forward at an angle of about 10 degrees. The blood pressure was 166 mm. Hg systolic and 100 mm. Hg diastolic. All motions of the right hip were moderately limited but painless. All borders of the left tibia were prominent, and the lower third of the left leg

Fig. 1.—Arteriograms of left lower extremity in case 1 show extensive degree of Paget's disease and increased vascularity; A, anteroposterior view and, B, lateral view.

was swollen and had a doughy consistency. The cutaneous temperature of the lower part of the left leg was greatly increased. A pulsating mass about 2 in. (5.08 cm.) in diameter was located 2 in. above and anterior to the lateral malleolus on the left. No bruit could be heard. Pulsations of the femoral, popliteal, posterior tibial, dorsalis pedis, ulnar, and radial arteries were all normal.

Results of routine laboratory tests were normal except for a grade 2 pyuria. The value for alkaline phosphatase in the serum was 19.0 King and Armstrong units, and that for acid phosphatase was 1.1 units. Roentgenograms of the lower extremities showed the presence of typical Paget's disease in the upper part of the right femur and the lower half of the left tibia.

The arteriograms showed a considerable increase in the collateral blood supply, especially about the periphery of the osseous lesion involving the distal half of the left tibia (fig. 1). No definite arteriovenous fistulas could be seen.

CASE 2.—A 52-year-old white salesman came to the clinic in May, 1952, because of pain in the left leg of one and a half years' duration. He first had noted a deformity of the left knee two and a half years previously; a roentgenogram of this region in 1950 showed evidence of osteitis deformans. The patient had aching of the upper part of the left tibia and swelling of the left leg when he was on his feet for any extended period. Relief was obtained by rest. He had little nocturnal pain. The history revealed no report of trauma to the left leg, but the man had sustained a fracture of the right leg at the age of 10 years.

The blood pressure was 136 mm. Hg systolic and 90 mm. Hg diastolic. A varus deformity of the left knee was present and was associated with some bony enlargement. Increased warmth was noted over the upper portion of the left tibia. No joint tenderness was present.

Results of routine laboratory tests were normal. The basal metabolic rate was -3%. The value for serum calcium was 9.5 mg. per 100 cc., and that for phosphorus was 3.1 mg. The alkaline phosphatase value was 15.1 King and Armstrong units. Roentgenograms showed the findings of Paget's disease

in the upper part of the left tibia with flaring of the upper portion of the tibia, probably caused by softening of the bone.

Arteriograms disclosed increased vascularity anterior to the upper portion of the left tibia (fig. 2). No definite arteriovenous fistulas could be seen.

CASE 3.—A 49-year-old white woman, a medical secretary, came to the clinic in February, 1953, stating that a year ago she had bruised the upper half of the right tibia. This region had remained slightly tender, and she complained of a sense of deep, diffuse discomfort in it. A sister had had Paget's disease of bone.

The patient's blood pressure was 112 mm. Hg systolic and 74 mm. Hg diastolic. Slight anterior prominence over the upper end of the right tibia was present; this region was tender and warm and showed a cluster of superficial veins. All peripheral arterial pulsations were normal.

Results of routine laboratory tests were normal. The value for serum phosphorus was 3.9 mg. per 100 cc.; the alkaline phosphatase value was 5.9 Bodansky units. Roentgenograms of the right leg showed evidence of Paget's disease involving the upper half of the right tibia with great thickening of the cortex. No arteriogram was done.

STUDIES OF CIRCULATION

The table shows the results of studies of circulation performed in cases 2 and 3. In case 2, a slight increase was noted in venous pressure, together with a substantial increase in the venous oxygen saturation of the extremity

Fig. 2.—Arteriogram of left lower extremity in case 2 shows Paget's disease of the upper part of the tibia and increased vascularity about the knee.

affected by osteitis deformans. The curve of Evans blue did not indicate a difference in circulation times between the two extremities, but this does not rule out the possibility of arteriovenous communications, especially multiple small ones. Differences in circulation times usually

are noted when large arteriovenous fistulas are present.³ The data in case 3 show perhaps a slight increase in venous oxygen saturation of the extremity affected by Paget's disease. It is possible that the early and minimal involvement of bone in this case was insufficient to cause the circulatory abnormalities observed in case 2.

COMMENT

One may consider an arteriovenous shunt as the cause of the increased vascularity shown by both arteriograms and by the significantly increased venous oxygen saturation and increased venous pressure of the affected extremity in case 2. Edholm and co-workers⁴ noted that, in addition to the abnormally high cutaneous temperature of the affected parts in Paget's disease, dilatation of the heart and signs of cardiac failure combined with a high pulse pressure were often present. They recorded a cardiac output of 13.3 liters per minute in such a patient; this is extremely high. (Normal output is about 4 liters per minute.) When the signs just enumerated are combined with an increased cardiac output, one must consider anemia or arteriovenous aneurysm as the most likely diagnosis.

Results of Circulatory Studies of Femoral Veins in Patients with Paget's Disease of Bone

Case	Lower Extremity	Venous Pressure, Cm. of NaCl Solution *	Curve of Evans Blue (T-1824)	Simultaneous Venous Oxygen Saturation, %
2	Right	6.8	Normal	62
	Left	8.0	Normal	91
3	Right	4.6	Normal	75
	Left	4.8	Normal	68

* Expressed as height of column of fluid extending above midvertical plane of thorax when patient is supine.

The patient observed by Edholm's group was not anemic and did not have a traumatic or congenital arteriovenous aneurysm. These investigators thought that arteriovenous communications in the bones affected by Paget's disease might well be the cause of the arteriovenous shunt. Therefore, they applied cuffs to the thigh at a pressure greater than systolic, inserted a catheter into the right auricle, and noted (1) decrease in right auricular pressure, (2) slowing of the pulse, (3) decrease in cardiac output, and (4) slight increase in diastolic pressure. Their observations appear to indicate that multiple arteriovenous shunts are present in bones affected by Paget's disease, because the same responses as those just mentioned occur after partial occlusion of the afferent vessels of an arteriovenous aneurysm.

Edholm and associates also measured the blood flow through the diseased bone by means of a modified Lewis-Grant plethysmograph and found it to be 20 times greater than the flow through normal bone; the normal rate was about 1 cc. per minute per 100 cc. of bone. Their data

indicated that an increase of blood flow in bone occurs in widespread Paget's disease that is of sufficient magnitude to produce effects on the general circulation similar to those resulting from free arteriovenous communications. They noted the absence of significant increases in cardiac output in two cases of localized Paget's disease. This suggests that it is only when the disease becomes widespread that the circulation as a whole is greatly increased; in such cases, signs of cardiac failure may develop.

Pereira Torres and Lazzari^{2b} also have reported a case of generalized Paget's disease of bone in which cardiac enlargement and failure were present. They considered the latter difficulties to be caused by an increased blood flow. They postulated that the increased blood flow was the result of numerous arteriovenous fistulas in the affected bone.

SUMMARY AND CONCLUSIONS

Studies were made in three cases of osteitis deformans to determine if arteriovenous fistulas were present in the diseased extremity. Arteriograms showed increased vascularity in the region of osteitis deformans but failed to reveal definite arteriovenous fistulas. Results of special studies in one case demonstrated increased femoral venous pressure and increased femoral venous oxygen saturation in the involved lower extremity. Similar studies in another case showed no increase in the femoral venous pressure and only slight increase in femoral venous oxygen saturation in the extremity affected by osteitis deformans.

These data appear to indicate that multiple small arteriovenous fistulas probably are present in Paget's disease of bone. The symptoms and signs of osteitis deformans, the results of special vascular studies, and the pattern of the arteriograms probably are dependent largely on the degree of bony involvement produced by this disease.

Fatal Transfusion Reactions.—While the benefits of transfusion far outweigh the risk, there is a significant hazard in the administration of stored blood. The mortality from blood transfusion has been estimated to be as great as or greater than that from an appendectomy. The three outstanding dangers are homologous serum hepatitis, reactions due to incompatible blood, and bacterial contamination. . . . The occasional contamination of stored blood is inevitable, since it is impossible completely to sterilize the skin through which the phlebotomy needle is inserted, and since there is no effective method of sterilizing blood once drawn without damage to the blood. While earlier reports indicated more frequent contamination, an incidence of 1 to 3 per cent may be expected in modern blood banks. These studies are based on cultures of blood incubated at 37 or 32° C. Many organisms detected at these temperatures are either arrested or killed at the temperature of storage of blood (4 to 7° C.), and therefore rarely produce serious reactions. On the other hand, certain gram-negative bacilli do not grow at temperatures of 32° C. or above, but multiply freely at the storage temperature of blood. It is this group of organisms that have produced the most serious transfusion reactions.—A. R. Stevens Jr., M.D., and others, *Fatal Transfusion Reactions from Contamination of Stored Blood by Cold Growing Bacteria*, *Annals of Internal Medicine*, December, 1953.

ISONIAZID THERAPY IN CUTANEOUS TUBERCULOSIS AND SARCOIDOSIS

Robert E. Holsinger, M.D.

and

John Eric Dalton, M.D., Indianapolis

The rather unsatisfactory results of previous therapies in cutaneous tuberculosis led us to investigate the newer agents introduced for the treatment of this disease in other organs. Because tuberculoderms are uncommon, it is difficult to assemble individually any large series of such cases for an evaluation of their curative plans. Thus, for our guidance, we turned to the larger therapeutic studies done on the more prevalent pulmonary forms of this malady, and we selected isoniazid for trial. Since sarcoidosis presents clinical and histopathological findings similar to tuberculosis and since it is also difficult to handle, we included two cases of this somewhat rare entity in this study.

NEWER ANTITUBERCULOUS AGENTS

The recent Veterans Administration, Army, and Navy Conference on Chemotherapy in Tuberculosis¹ contributed much to our better understanding of the newer antituberculous agents. This group seems agreed that amithiozone (Tibione)^{2a} is too toxic to warrant further employment. This is likewise true of iproniazid^{2b,c} and viomycin,^{2d} although some workers feel that the former drug may have a limited use in producing a more rapid therapeutic response in the desperately ill patient with far advanced pulmonary tuberculosis^{2b} and that the latter agent, although possessing less antituberculous activity than streptomycin, may have some value in the treatment of the streptomycin-resistant phthisic patient.^{2d}

A final evaluation of both pyrazinamide (Aldinamide), and candicidin is awaited. Although some observers contend that pyrazinamide may serve in preparing tuberculous patients for surgery,^{2e} others believe that its early inducement of resistance^{2b} may prevent a continuance of its use. Furthermore, the producers of candicidin are seeking a greater purification of their crude preparation, which may reduce its untoward reactions and permit its use as a highly effective agent against *Candida* and the other yeast-like organisms affecting the lungs.^{2f}

Chlortetracycline (Aureomycin),^{2g} oxytetracycline (Terramycin),^{2h} and erythromycin²ⁱ seemingly do not produce severe toxic effects, but they also apparently have no destructive action on the *Mycobacterium tuberculosis*. Thus, the majority of the chest physicians have discarded them as antituberculous agents. Nevertheless, one investigator^{2h} states that phthisic patients given

streptomycin and oxytetracycline respond as well as those receiving streptomycin plus *p*-aminosalicylic acid and that the employment of the ordinary dose of 1 gm. of oxytetracycline daily is borne better than the usual 12 gm. of *p*-aminosalicylic acid daily. Therefore, he concludes that oxytetracycline can be substituted, without the loss of therapeutic effect, for persons who do not tolerate *p*-aminosalicylic acid.

Several new observations on *p*-aminosalicylic acid were recorded at the recent conference in Atlanta. A group of workers^{2j} noted that the enteric-coated preparations of this drug were often passed in the stool and that this could account for certain treatment failures. Also it was reported that a solution of the sodium salt of *p*-aminosalicylic acid is therapeutically more effective than the granules or capsules of this medicament. Furthermore, a slight but definite increase in prothrombin time, without any change in coagulation time, was described in a small series of patients treated with *p*-aminosalicylic acid,^{2j} but in another large group of patients who received this drug just prior to surgery, no abnormal bleeding tendency was observed. It was suggested, however, that the prothrombin time should be determined before any surgical procedure on any person receiving *p*-aminosalicylic acid and that vitamin K₁ should be given if the test is abnormal.^{2j} In addition, it was demonstrated that *p*-aminosalicylic acid has some antithyroid activity, which was indicated by an early diminution in the iodine uptake by the thyroid gland and that may progress during the first month of treatment, but which thereafter remains stationary.^{2k}

A review of the recent studies on streptomycin yielded some new data. In an attempt to improve this agent, a *p*-aminosalicylic acid salt of streptomycin was developed, but it had no more merit.^{2l} In addition, there was a report on some brief experiences with the action of various streptomycyclamine derivatives of streptomycin.^{2l} They found one compound (N'-n-octadecylamine of streptomycin) that had a fair degree of antitubercular activity but the other members of this group were either inferior to it, were neutral in action, or actually supported a growth of *Myco. tuberculosis*. In a large study to evaluate the comparative merits of streptomycin and dihydrostreptomycin, it was recorded that there is no difference in the therapeutic results obtained with either of these two preparations.^{2m} However, because streptomycin tends to damage the vestibular apparatus and because dihydrostreptomycin tends to harm the auditory function, it seems advisable to alternate them in the injection series or to routinely use a preparation (Distrycin) containing equal parts of the two agents.^{2n,o} Furthermore, this procedure may reduce other allergic phenomena that occur with greater frequency and severity with streptomycin. Also, a report on the tissue concentra-

From the Department of Dermatology and Syphilology of Indianapolis General Hospital, the Alembert Winthrop Brayton Skin and Cancer Foundation, and its allied P. C. Reilly Laboratory of Mycology.

Owing to lack of space, the bibliographic references have been omitted from THE JOURNAL and will be included only in the authors' reprints.

Read before the Section on Dermatology and Syphilology at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

Much of the information on the newer antituberculous agents was obtained from the notes of Drs. J. W. Smith and J. G. Evans of the Lilly Research Division of Indianapolis General Hospital on the Veterans Administration, Army, and Navy Conference on Chemotherapy in Tuberculosis held at Atlanta, Ga., on Feb. 9 to 12, 1953.

tion of streptomycin¹⁰ showed that there was as much as 0.5 mcg. per milliliter of tissue of the agent present in the lungs three days after the last injection in patients receiving 1 gm. of the drug daily.

In the continuing cooperative study of the Veterans Administration, Army, and Navy, which is aimed at finding the most effective treatment regimen for pulmonary tuberculosis, it has been agreed that a combination of biweekly intramuscular injections of 1 gm. of streptomycin or dihydrostreptomycin and daily oral administrations of 12 gm. of *p*-aminosalicylic acid, divided into four spaced 3 gm. doses is as effective as any of the regimens.¹² In one investigation¹¹ the accepted streptomycin schedule was simplified by use of 2 gm. doses of that agent once weekly, but this led to immediate bothersome side-effects of flushing and perioral paresthesias. In a limited study, another group¹² experimented with a single daily dose of 6 gm. of *p*-aminosalicylic acid to replace the giving of the four 3 gm. amounts of this drug, and they report a better toleration and equally good results from this modification.

HISTORY OF ISONIAZID AS ANTITUBERCULOUS DRUG

In 1912, two German chemists² were prompted to follow up the experiments of some earlier workers³ and this resulted in the first production of isonicotinic acid hydrazide, which is now called isonicotinyl-hydrazine or isoniazid, the generic name adopted by the A. M. A. Council on Pharmacy and Chemistry. At that time it was merely an interesting, new, colorless, crystalline, small-molecular, water-soluble, pure, synthetic compound bearing a formula of $C_6H_7N_3O$ and having no known use.

Then in 1945 two Frenchmen⁴ (E. Huant and V. Chorine) published separately reports on the antituberculous activity of nicotinamide. One of them (Chorine) concluded that this activity was not a vitamin result because he could not show the basic nicotinic acid to have tuberculostatic properties. Although the work of these men was forgotten, the action of nicotinamide against the tubercle bacillus was rediscovered by two Americans⁴ (McKenzie and Kushner) in 1948, but they believed this was a vitamin effect because they found that only nicotinamide derivatives that jointly possessed vitamin and tuberculostatic activity showed this antituberculous quality. These particular studies were discontinued because none of the nicotinamide derivatives that they developed were as good or more effective than nicotinamide. Nevertheless, it did stimulate research with the pyridine carboxylic derivatives,⁵ and this led to the eventual introduction of isoniazid as a drug that is cheap, orally administered, relatively atoxic, and tuberculostatic.⁶ It is available under such trade names as Nydrazid, Rimifon, Dinacrin, and I. N. H.

IN VITRO STUDIES WITH ISONIAZID

In vitro experiments⁷ with isoniazid have shown that, even in low concentrations, it has a specific and destructive effect on both extracellular and intracellular Myco. tuberculosis organisms, but it is ineffective against common gram-negative and gram-positive bacteria and only moderately active on small fungi.⁸

IN VIVO STUDIES WITH ISONIAZID IN ANIMALS

In vivo studies have demonstrated that isoniazid is effective in arresting or curing tuberculous processes in guinea pigs,⁹ mice,¹⁰ monkeys,¹¹ and rabbits¹²; that it is well tolerated by animals when given in proper amounts¹³; and that it is less toxic than other isomers of nicotinic acid.¹⁴ However, large doses of the drug could produce toxic phenomena of anorexia, jaundice, weight loss, nervous excitement, tremors, ataxia, convulsion prostration, and death in acute respiratory failure.¹⁵ In dogs, most of these reactions were reversible, and there was a definite relationship between plasma peaks and toxicity. High doses also led to changes in the red and white blood cell counts and the hemoglobin levels, but prolonged lower dosages of the drug caused no alterations in those blood elements.¹³

ISONIAZID THERAPY IN TUBERCULOSIS IN MAN

After extensive test tube and animal studies had proved that isoniazid possessed high antituberculous qualities and could safely be given to man, physicians began to use this drug in therapeutic studies on tuberculous patients. Since its advent, numerous reports have appeared on its administration in a wide variety of the forms of this disease with varying degrees of involvement.

Isoniazid in Pulmonary Tuberculosis.—The earliest clinical investigators¹⁶ of isoniazid gave this drug alone to several patients with advanced and therapeutically unresponsive disease, and they observed x-ray, clinical, and laboratory improvements, consisting of lessened cough, lowered temperature, improved roentgenological findings, decreased Gaffky counts, some negative sputums, and increased weight. Also they observed no gastrointestinal irritation, allergic phenomena, or altered kidney, liver, or heart function. Furthermore, their subsequent reports¹⁷ have continued to be favorable. Later,¹⁸ another group found that this drug alone or with streptomycin produced better roentgenological clearing than did a combined streptomycin and *p*-aminosalicylic acid form of therapy, but they failed to note much difference between these three plans in the clinical or laboratory betterment of the patients. Likewise, other workers¹⁹ in this field have recorded generally beneficial results.

However, certain skeptical voices have arisen, and a recent preliminary report²⁰ states that a three to five month schedule of therapy with streptomycin and *p*-aminosalicylic acid produces a better therapeutic result than a program of isoniazid alone or with streptomycin. Another group²⁰ found that in 33% of a series of 114 cases negative sputums developed following isoniazid treatment but over-all clinical improvement was apparent in only 10 to 11%. In some instances, the symptoms became severer during this treatment. Other workers²¹ disagree with the earlier reports of betterment in the roentgenological, clinical, and laboratory findings and even believe^{21a} that there is a higher relapse rate among isoniazid-treated patients. Some investigators feel that the drug's action is on the systemic toxicity rather than on the particular tuberculous lesion²² and that any recorded increase in appetite is a nonspecific drug effect.²⁰ In all of these evaluations it has been cautioned

that the continued values of bed rest, other supportive treatment, and the patient's own capacity to combat the infection not be forgotten.¹⁸

Isoniazid Therapy in Extrapulmonary Tuberculosis.—Furthermore, treatment with isoniazid has been beneficial in laryngeal,²³ otic,²³ gastrointestinal,²³ genitourinary,²⁴ tongue,²⁵ uveal,²⁶ meningeal,²⁷ and miliary forms^{27b} of this disease. A recent group discussion^{18,28,29} on the treatment of meningeal and miliary tuberculosis concluded that *p*-aminosalicylic acid and streptomycin is still the best combination for these manifestations, but it

Fig. 1.—Tuberculosis cutis luposa in a 34-year-old Negro housewife. A, on March 8, 1952, at institution of therapy. B, on May 7, 1953, after treatment with streptomycin, *p*-aminosalicylic acid, and isoniazid.

was admitted that isoniazid had been tried in too few cases to definitely exclude it from the therapy of those forms.

Isoniazid Therapy in Cutaneous Tuberculosis.—The first report²⁸ on the use of isoniazid therapy in cutaneous tuberculosis came from Bonn, Germany, where in several cases previously unresponsive patients with tuberculosis cutis of the luposa, verrucosa, colliquative, and papulonecrotica types attained good healing and no untoward reactions with oral administration of doses of from 5 to 10 mg. per kilogram of body weight per day of this drug. This publication was followed shortly by a report²⁹ in this country in which clinical healing was secured in one case of tuberculosis cutis luposa by giving dosages of 4 mg. per kilogram daily of the agent. Since that time one other similar article³⁰ has been published, and an earlier accepted preliminary observation by one of us (R. H.)³¹ on the joint clinical and histopathological benefits obtained from this drug in a case of lupus vulgaris has appeared.

DOSE SIZE, TREATMENT SCHEDULES, AND DURATION FOR ISONIAZID THERAPY

To determine the proper isoniazid dosage for man, several laboratory animals (dogs, mice, and rats) were subjected to acute and chronic toxicity studies by several investigators.³² From these experiments it was determined that the tolerated daily oral dose of isoniazid is related to the relative body surface areas of the different species. Thus, extension of their calculations to man indicated that amounts of 4 to 5 mg. per kilogram daily are safe for human beings. However, clinicians^{17b} began by administering 2 mg. per kilogram daily, but this dosage was gradually increased to the presently recommended quantities of 3 to 5 mg. per kilogram daily.³³ The safety and efficacy of this schedule was predicted on

the knowledge that the drug is absorbed readily from the alimentary tract,³⁴ penetrates quickly and widely into the tissues,^{35a} is excreted rapidly by the kidney and bowel,^{35b} and fails to accumulate unduly in the body.³⁴

Lately, a cooperative study group¹ has recommended the use of 6 or more mg. per kilogram daily for better therapeutic results, and the literature shows that some clinicians²⁸ had already done this in small series of cases without untoward reactions. However, some investigators¹⁸ insist that better responses occur with less than 5 mg. per kilogram daily.

To conduct a pure study,³⁶ early workers used isoniazid alone, but it was later reported¹⁸ that the improvement was not maintained if isoniazid was used alone for longer than three months. Thus, an accumulated experience³⁷ indicated that a superior therapeutic effect was achieved only when the drug was used with streptomycin or *p*-aminosalicylic acid or both, although patients on these combined regimens may show a greater number of toxic reactions than those receiving isoniazid alone.¹⁸ Therefore, for the present, the customary program is to use 3 to 5 mg. per kilogram daily of isoniazid orally plus 1 gm. biweekly of streptomycin or dihydrostreptomycin intramuscularly. Recently, a new preparation containing equal parts¹⁸ of streptomycin and dihydrostreptomycin was introduced, and this may reduce the vestibular damage or auditory harm that may result from use of these two agents.

Finally there has been a preliminary report³⁷ on the use of radioactive isoniazid. One observer noted an accumulation of this special preparation in the lungs, skin, and caseous material of tuberculous lesions, but no elevated peak in the serum level. Another investigator believes that this substance cannot be metabolized by sensitive organisms and thus destroys those bacteria, whereas resistant organisms use the drug as a source of food.

Fig. 2.—Tuberculosis cutis colliquativa in a 69-year-old woman. A, on Oct. 18, 1952, at time of first biopsy. B, on Jan. 23, 1953, after treatment with isoniazid and streptomycin.

It would seem that isoniazid can be given over indefinite but long periods with relative safety. However, there is no settled opinion on how long it should be given after the apparent healing of the active lesions.

REACTIONS AND CONTRAINDICATIONS TO ISONIAZID THERAPY

In an early report¹⁶ on the use of isoniazid alone in pulmonary tuberculosis, reactions of mouth dryness, nausea, vomiting, constipation, hyper-reflexia, muscular twitchings, bladder flaccidity, vertigo, drowsiness, and

insomnia were noted, but these signs disappeared with continuance of therapy with the drug. Furthermore, they¹⁶ observed mild eosinophilia and a slight decrease in hemoglobin levels, but they found these to be reversible. Another study²⁰ revealed elevated temperatures, increased sputum, worse chest lesions, and exudative reactions in some persons who were treated with this drug. Also, an increased coagulation time, without any change in the bleeding or the prothrombin time, and increased bleeding tendencies have been reported in

Fig. 3.—Tuberculosis cutis papulonecrotica in a 15-year-old white student. A, appearance on Dec. 6, 1952. B, lesions on May 7, 1953, after failure of treatment with isoniazid, streptomycin, and *p*-aminosalicylic acid. C, photomicrograph of biopsy specimen obtained Dec. 6, 1952. D, photomicrograph indicating failure of treatment on May 7, 1953.

some patients during isoniazid therapy.³⁸ Additional reactions of acute pellagra,³⁹ confusional psychoses,⁴⁰ aggravation of epileptic seizures,⁴¹ and the possibility of toxic hepatitis⁴² with jaundice have been recorded.

The only published dermatological manifestation⁴³ from this drug is a case of cutaneous sensitization developing in a pharmaceutical chemist who handled this drug. With this report it will behoove us to watch physicians, nurses, druggists, and others who have repeated contact with isoniazid.

No absolute contraindication to the existing isoniazid therapy has been observed, but severer reactions may be encountered with the newly recommended, increased doses of this drug. If any question arises, it would be well to decrease the dosage or discontinue administration of the drug in accordance with the severity or continuance of the sign. One group⁴⁴ believes that persons with marked central nervous system stimulation from the drug or epilepsy may be treated by concurrent oral administration of phenobarbital or pentobarbital if the toxic symptoms are acute. They⁴⁴ also caution against the use of central nervous system stimulants such as belladonna, ephedrine, or epinephrine in these particular cases. Also

any poor appetite, such as existed in the reported case of pellagra, should be bolstered by vitamin B complex.³⁹ Another worker,¹⁵ in the field of genitourinary tuberculosis, noted that higher blood levels of isoniazid may occur in patients with elevated blood urea levels, but that this is not a contraindication to the continuance of full doses of this drug.

ISONIAZID THERAPY AND DRUG RESISTANCE TO TUBERCLE BACILLI

When streptomycin-resistant organisms develop, then a combined regimen of isoniazid and *p*-aminosalicylic acid is reportedly superior to isoniazid alone^{1a} and the former drug is seemingly less effective than the latter agent in preventing the emergence of resistance to streptomycin.¹⁵

A resistance to isoniazid may appear rapidly⁴⁵ if this is used alone. This was seen in a recent study⁴⁶ of a series of cases of isoniazid-treated pulmonary tuberculosis in which bacillary resistance occurred in 11% by the end of the first month, in 52% by the end of the second month, and in 71% by the end of the third month. Furthermore, this arrested improvement⁴⁶ was shown in the repeated clinical and x-ray examinations.

These bad results can often be avoided by using isoniazid and streptomycin concurrently.⁴⁷ Also one

Fig. 4.—Sarcoidosis in a 37-year-old Negro woman. A, clinical appearance on Jan. 22, 1953. B, clinical appearance after treatment with isoniazid. C, photomicrograph of specimen obtained Dec. 23, 1952, on which diagnosis was based. D, photomicrograph showing lack of change in lesion with treatment.

group recently recommended an alternating schedule of isoniazid alone for one month, then streptomycin plus *p*-aminosalicylic acid for one month, then isoniazid alone for one month, and then streptomycin plus isoniazid for four months. With this regimen they did not find resistant organisms in any case.¹⁸

When isoniazid-resistant organisms emerge, the improvement in the patient's clinical condition usually re-

mains stationary or further improves and less frequently relapses.¹² As an example of this, a recent study reported on 15 patients with avirulent, isoniazid-resistant organisms; in 13 cases the tuberculosis remained improved and in only 2 worsened. Furthermore,¹² although the bacilli are considered resistant, there may still be improvement with continued isoniazid therapy. However, the mortality rate¹¹ is higher in this group than in those whose organisms have remained sensitive to this drug.

It also seems that, when organisms become resistant to isoniazid, then they also become avirulent to guinea pigs and possibly to human beings. However, considerable discussion can be provoked on whether avirulence means death of the bacilli or whether the nonviable organism can again later regain its power of viability and reproduction under some undescribed change in their condition or environment.¹²

ISONIAZID THERAPY IN CUTANEOUS TUBERCULOSIS AND SARCOIDOSIS

The effect of isoniazid therapy was studied in eight cases of tuberculosis cutis, including three of luposa, one of colliquativa, two of papulonecrotica, and two of micropapular types of this disease and two additional cases of sarcoidosis. Prior to beginning of treatment for each patient a thorough history was obtained and physical examination done. Laboratory studies included a red blood cell count, a total and differential white blood cell count; a hemoglobin determination, a urinalysis, tuberculin reaction studies, a diagnostic roentgenogram of the chest, a roentgen study of the long bones, if indicated, a cutaneous biopsy, and a clinical photograph. During the period of their observation, each patient had frequent clinical examinations, periodic biopsy studies, and clinical photograph retakes. Thus, to conserve space, we will record only the pertinent history, the physical changes, the positive laboratory results, and the procedural variances in our reports of the individual cases. Moreover, owing to lack of space, the number of photographs is limited.

The routine treatment for all patients consisted of the oral administration of 4 mg. per kilogram daily of isoniazid. In some patients other antituberculous agents were added to this program, and the particular details of those modified regimens are given in the individual case records.

REPORTS OF CASES

CASE 1.—In 1926, a tall, slender, 34-year-old Negro housewife noted a single small cluster of diascopy-positive, asymptomatic, dull red, small papules of the left malar eminence. This persisted and gradually spread into a large, solid triangular patch, involving widely the left cheek, temple, and outer canthus of the eye and eventuating in a central scar with peripheral activity. Topical and vitamin D₂ therapy had failed. A positive tuberculin test and a biopsy on Sept. 5, 1946, confirmed our clinical diagnosis of tuberculosis cutis luposa.

On March 8, 1952, biweekly injections of 0.5 gm. of streptomycin were begun and a clinical photograph made (fig. 1A). On March 18 four daily oral doses of 22½ grains (1.5 gm.) each of *p*-aminosalicylic acid were added and these were gradually increased to 45 grains (3 gm.). Since these drugs failed to benefit, they were stopped, another biopsy specimen was obtained and routine isoniazid therapy was begun on April 30. Another biopsy on June 24 revealed a subsiding pathological process, and by Oct. 6 the process appeared to

be clinically cured. However, the isoniazid therapy was continued regularly until Jan. 30, 1953, and then discontinued. After this stoppage of all treatment, the arrest has been maintained, as indicated by the clinical photograph (fig. 1B) of May 7. This case was reported in detail earlier.¹¹

CASE 2.—In 1891, while still residing in his native Poland, the short, stocky patient, a 67-year-old white tailor, had an asymptomatic eruption on the left side of the face. It was diagnosed as lupus vulgaris and persistently extended to cover rather solidly the face, nose, ears, scalp and neck, with an intermittently active and scarring process containing diascopy-positive apple-jelly papules. A positive tuberculin test and a cutaneous biopsy of Sept. 13, 1952, confirmed the clinical diagnosis of tuberculosis cutis luposa. Between Oct. 17 and Nov. 21, 1952, he received biweekly injections of 1 gm. of dihydrostreptomycin. On the latter date, another biopsy was done and routine isoniazid therapy was started. This had been continued to the time of writing, and, although there had been marked improvement some clinical and histopathological activity remained.

CASE 3.—In 1944, the patient, a short, well-nourished, 44-year-old white housewife, had a small cluster of a few scattered, asymptomatic, pinkish, diascopy-positive, small papules of the left malar area. Because additional lesions continued to appear, she consulted her family physician, who did a biopsy that was reported as showing chronic dermatitis. A subsequent biopsy on Jan. 12, 1951, by a colleague in dermatology confirmed an impression of lupus vulgaris, but topical applications and vitamin D₂ therapy failed. In 1940 pulmonary tuberculosis was diagnosed and she was treated for pulmonary tuberculosis, and in 1942 that process was declared arrested. The positive Mantoux test and repeat biopsy on March 17, 1953, confirmed our impression of tuberculosis cutis luposa. A chest roentgenogram showed no tuberculous activity in the lungs. On March 19 routine isoniazid therapy was begun, and on March 26 biweekly injections of 1 gm. of dihydrostreptomycin were added, but on April 20 we replaced the latter drug with biweekly injections of 1 gm. of a combination of streptomycin and dihydrostreptomycin (Distreptocin) sulfate. She has had remarkable clearing.

CASE 4.—The patient was a small, slender, 69-year-old, white widowed housewife. About Aug. 20, 1952, an asymptomatic, nut-sized, doughy, indolent, subcutaneous tumor was discovered just above the center of the right clavicle. When the overlying skin became inflamed in a short time, her physician lanced the tumor and obtained only scanty serous fluid. Thereafter, this opening ulcerated; a seropurulent discharge appeared; thin blood surface crusts formed; and pallid granulations occurred at the base. On Sept. 23 a biopsy specimen showed a tuberculous picture with pseudoepitheliomatous hyperplasia and a tuberculin test was positive. Chest roentgenograms demonstrated old fibrotic calcifications in both apexes and the hilar regions of the lungs and a spot film showed an increased density in the right third rib posteriorly at its juncture with the transverse process. Iodopyracet (Diodrast) injected into the neck sinus anteriorly trickled back and down to puddle about the rib thickening posteriorly. A guinea pig inoculation was positive for tuberculosis. Thus, a diagnosis of tuberculosis cutis colliquativa was made.

On Oct. 18 an initial biopsy was done, and on Nov. 13 a clinical photograph (fig. 2A) was made. On Oct. 23 routine isoniazid (I. N. H.) therapy was undertaken, with daily injections of 1 gm. of streptomycin and a check photograph (fig. 2B) on Jan. 23, 1953, was made. In mid-March, 1953, the streptomycin injections were reduced to a biweekly schedule because of vertigo, and she has been continued on this modified program to date. On her return home in February, 1953, she passed from our direct care, and for that reason there are no check biopsies or later clinical photographs. However, we have kept in contact with her present physician, and he reports that the sinus was firmly healed by April, 1953.

CASE 5.—In mid-February, 1952, the patient, a medium-tall, moderately heavy, 15-year-old white student noted an asymptomatic eruption of pinkish, deep papules. The eruption progressed to central pustulation and necrotization and eventuated in small depressed scars with a pigmented halo, or some-

times in keloids. There was a simultaneous appearance of lesions over the trunk, buttock, extremities, and neck and a few on the face. A tuberculin test was strongly positive, and a section of the skin obtained on Dec. 6, 1952 (fig. 3C), was consistent with our clinical diagnosis of tuberculosis cutis papulonecrotica. A clinical photograph (fig. 3A) on Dec. 6 shows a picture similar to that on her admission. A subsequent consultation with her internist failed to divulge a tuberculous focus in this patient, and a full investigation of her family failed to show tuberculosis in any member.

On June 21 routine isoniazid therapy was begun, and on Sept. 27 biweekly injections of 1 gm. of streptomycin were added to the program. These therapies have been carried regularly to date, but new lesions continue to develop. Lately, although not reacting to streptomycin, she was changed to a combined program of isoniazid and *p*-aminosalicylic acid. This treatment failure is indicated in the clinical photograph (fig. 3B) and the photomicrograph (fig. 3D) of May 7, 1953.

CASE 6.—In August, 1952, this medium-tall, obese, 49-year-old white man had a sudden single outcropping of asymptomatic papulopustular lesions scattered over both lower extremities. These persisted and led to a central pustulation and necrosis with eventual centrally pitted scars, which had surrounding pigmentation. There was a history of chorioretinitis of unknown cause in 1947. A tuberculin test positivity and a suggestive tuberculous picture in the biopsy led a colleague in dermatology to make the clinical diagnosis of tuberculosis cutis papulonecrotica. On Nov. 22 routine isoniazid therapy was begun, with biweekly injections of 1 gm. of dihydrostreptomycin. On Jan. 23, 1953, the administration of dihydrostreptomycin was stopped, but the isoniazid was given alone for an additional month, when all medication was stopped. The process cleared, and no new lesions have appeared.

CASE 7.—In early 1946 a moderately tall, slender, 32-year-old white housewife noted asymptomatic, pinkish-yellow, barely elevated, very small papules. They were scattered and grouped about the forehead, cheeks, chin and upper neck, and led to minute depressed scars. Other physicians had treated this as a contact or food allergy, and she complained of considerable nervousness for which she had earlier taken sedatives. On Feb. 2, 1948, a biopsy showed only one small area of epithelioid reaction, and the tuberculin test was only slightly positive. After consultation with a dermatologist, a diagnosis of micropapular tuberculid was made. Between Feb. 7, 1948, and Dec. 2, 1952, she received fairly continuous vitamin D₂ therapy, and the lesions improved but never cleared. On Dec. 2 routine isoniazid therapy alone was begun, and this has been continued to date. Early in the treatment the response was slow, but later the process showed definite clinical improvement; she refused a check biopsy.

CASE 8.—In early 1950, a moderately tall, moderately heavy, 35-year-old white housewife had pruritic, erythematous, small, deep papules in the lateral portions of both cheeks. Earlier she had had acne vulgaris, and she still complained of an occasional pimple. Of herself, she had used several topical proprietaries, but she admitted no drug ingestion. A chest roentgenogram showed several calcified right hilar nodes, a midright lung Ghon complex, and marked right base bronchovascular markings. A tuberculin test was moderately positive. A biopsy specimen on Jan. 1, 1951, was compatible with micropapular tuberculid, and we made a clinical diagnosis of the same entity. Between Feb. 7 and Dec. 15, 1952, she received rather continuous vitamin D₂ therapy with moderate improvement, but the discomforts of a pregnancy temporarily interrupted her treatment and observation. However, she returned with a flare-up on March 23, 1953, and routine isoniazid therapy alone was begun, which has been continued to date. She was essentially free of her eruption when last seen, but she refused a check biopsy.

CASE 9.—From Aug. 1, 1952, to the time of writing, a tall, slender, 31-year-old white housewife had had six asymptomatic lesions of the forehead and cheeks. They were split-pea-sized, pinkish-yellow-brown solid lesions that were elevated peripherally. Her tuberculin test was negative, and roentgenological studies of the chest and long bones revealed no abnormalities. A biopsy performed on Feb. 3, 1953, confirmed

our clinical diagnosis of sarcoidosis. On Feb. 24, 1953, routine isoniazid therapy alone was begun and has been continued to date. No clinical improvement had occurred by May 11.

CASE 10.—On Aug. 25, 1952, a medium-tall, slender, alert, 37-year-old Negro housewife entered our tuberculosis division. She had had a dry cough for two years, fatigue for 1½ years, a skin eruption for one year, voice huskiness and dyspnea for six months, a weight loss for three months, and recurrent hemoptysis for 10 days. After admission she failed to bleed further and the physical chest signs cleared promptly, but the huskiness, dyspnea and skin eruption persisted. Her skin eruption consisted of dull-red, firm, single or grouped papules about the nares, nose angles, and eyelids; there were patchy or linear arrangements about the right forehead, the left mandibular area, the right elbow extensor, and the posterior right side and anterior neck. A laryngoscopic examination revealed thickening of the left vocal cord and ulcerations of the epiglottis, the aryepiglottic folds, and the arytenoid cartilage. Results of tuberculin tests with increased concentrations, sputum examinations, a histoplasmin test, and blood serologic studies were all negative. Repeated chest roentgenograms were interpreted as showing tuberculosis, but on a later review these were adjudged compatible with atypical sarcoidosis. The microscopic examination of laryngeal tissue lay between tuberculosis and sarcoidosis, but a cutaneous biopsy specimen (fig. 4C) on Dec. 23 was consistent with the latter. Thus, in considering all findings, a diagnosis of sarcoidosis was made. On Jan. 22, 1953, a clinical photograph (fig. 4A) was made. On Jan. 5 routine isoniazid therapy was started alone, and this has been continued to date. Although a clinical photograph (fig. 4B) and a photomicrograph (fig. 4D) on May 11 showed the skin eruption to be unaltered, the consulting chest physician believed the lung picture looked better, although he added that this may sometimes be a transitory phase in this disease.

SUMMARY

In the true tuberculoderms, two patients (cases 1 and 3) with tuberculosis cutis luposa and one patient (case 4) with tuberculosis cutis colliquativa obtained excellent therapeutic results with isoniazid administered alone or in combination with streptomycin or dihydrostreptomycin. However, another patient (case 2) with tuberculosis cutis luposa showed only a good but incomplete response to isoniazid and dihydrostreptomycin, but we believe that his marked residual scarring would have slowed the penetration of any chemotherapeutic agent.

In the last two cases of tuberculosis cutis papulonecrotica, one patient (case 6) had prompt and complete disappearance of his lesions with isoniazid plus dihydrostreptomycin and the lesions have remained clear after discontinuance of therapy. The condition of the other patient (case 5) has worsened during treatment with isoniazid combined with streptomycin and *p*-aminosalicylic acid. However, it is possible that the former patient, a middle-aged man, was more careful of his rest and general living than the latter patient, a high school girl. In the two cases of micropapular tuberculid (cases 7 and 8), both patients showed a slow response to isoniazid therapy alone but when last seen they were showing definite signs of improvement and the skin of one of them is essentially clear (case 8). In the two cases of sarcoidosis (cases 9 and 10), there was no cutaneous improvement after administration of isoniazid alone. However, the pulmonary clearing reported by the consultant in case 10 is yet to be fully evaluated.

We feel that all reported progress should be checked by both clinical and histopathological studies. Our much too limited study seemed to indicate that one can expect a faster and better therapeutic result with isoniazid in

the true tuberculoderms than in the tuberculids. This is not a rigid statement, however, and we ask other workers to check on this preliminary observation.

Our limited study showed no untoward reactions ascribable to isoniazid and an ordinarily prompt therapeutic response, when used in oral doses of 4 mg. per kilogram of body weight per day, but we regret the vestibular damage produced by streptomycin in case 4. Furthermore, it would seem that this drug can be employed over indefinitely long periods. One must watch

for isoniazid resistance, however, although no relapse occurred in our series after the condition of a patient had once cleared. It is now agreed that this agent is best used in combination with streptomycin or dihydrostreptomycin or a combination of streptomycin and dihydrostreptomycin (Distreptocin) sulfate and possibly *p*-aminosalicylic acid, and we do recommend the further trial of this drug in combination for cutaneous tuberculosis and sarcoidosis.

Locke and 10th St. (Dr. Dalton).

NEWER APPROACHES TO THE STUDY OF HEMOPHILIA AND HEMOPHILIOID STATES

Kenneth M. Brinkhous, M.D., Robert D. Langdell, M.D., George D. Penick, M.D., John B. Graham, M.D.

and

Robert H. Wagner, Ph.D., Chapel Hill, N. C.

Recent studies have shown that hemophilia, even if severe and classical in type, may be easily confused with other hemorrhagic states. Severe hemorrhagic manifestations, including repeated hemarthroses, a family history suggesting a sex-linked recessive inheritance, and laboratory findings, such as a long clotting time, normal prothrombin time, and delayed prothrombin utilization, may all be present; yet the disease may not be true hemophilia. On the other hand, it has been shown that hemophilia may be so mild that the diagnostic procedures in common use are inadequate for diagnosis.

In the last few years many cases of hemophilia-like disease, different from either the severe or mild forms of hemophilia, have been described. As in hemophilia, there is a bleeding tendency from childhood, and often there are other bleeders in the family. The clotting defects shown by these patients are of several different types. They resemble hemophilia in that there is ineffectual conversion of prothrombin to thrombin. At least four distinct hemophilia-like hemorrhagic diseases, apparently due to a deficiency of one of four separate plasma clotting factors, have been described. These diseases form a group that we term the hemophilioid states. In this paper two new methods for the diagnosis of hemophilia are considered along with a simple procedure for the differentiation of hemophilia and the various hemophilioid states.

METHODS

The two new methods for the diagnosis of hemophilia are (1) the partial thromboplastin time (PTT) and (2) a simplified antihemophilic factor (AHF) assay procedure. The partial thromboplastin time¹ is performed at 37 C by mixing 0.1 ml. of oxalated plasma, 0.1 ml. of partial thromboplastin (either crude cephalin or Asolectin²), and 0.1 ml. of 0.02 M calcium chloride, in the order named. The concentration of partial thromboplastin is adjusted by dilution to give a clotting time in the range of 40 to 80 seconds; 0.3% suspension is usually satisfactory.

The AHF assay has been described in detail by Langdell, Wagner, and Brinkhous.¹ Results are expressed in per cent of normal. The 100% value is that of a care-

fully selected person whose AHF activity is about that of the mean of a larger group of normal adults. The prothrombin time and the two prothrombin utilization (or consumption) methods have been described previously.³ Clotting times were done by the two tube Lee-White method. Bleeding times were performed by Ivy's method.

PATIENTS WITH HEMOPHILIA AND SUBHEMOPHILIA

The use of the two new laboratory procedures, the partial thromboplastin time and the AHF assay is illustrated in three cases of hemophilia of different degrees of severity. Included in the study is a "normal" subject who had one episode of abnormal bleeding postoperatively. This subject is representative of a group we have called subhemophilia, which will be considered below.

Classical Hemophilia.—A 28-year-old taxi driver (T. W. T.) bruised easily all his life. He had "arthritis" for many years. Hemarthroses occurred in many joints, and the right knee was immobile. Severe internal hemorrhage five years prior to our study required numerous transfusions. He had two brothers, both of whom were "bleeders," five normal sisters, and one normal son. During childhood he was told he had hemophilia.

Moderate Hemophilia.—A 69-year-old retired college professor (H. A. D.) had frequent bruises and occasional large hematomas all his life. At the age of 8 he bled for several days after a sling shot injury to the forehead. As a college baseball player, at the age of 25, he injured his

left hip during play and had recurrent swelling and pain at the age of 45. At the age of 57 he bled for 10 days from the operative wound after hemorrhoidectomy. After tooth extractions, he always bled for several days. He was told on two occasions during the past 15 years, after blood studies, that he had vascular purpura. He had no transfusions. No other members of the family were similarly affected.

Mild Hemophilia.—An 18-year-old college student (V. McF.) bruised easily all his life. After tonsillectomy at the age of 5 and after a fall at the age of 6 in which two teeth were knocked out, he bled for many days and was given blood transfusions on both occasions. At the age of 9 he was hospitalized for one week because of bleeding after a tooth extraction. He was given one transfusion. There were no hemarthroses. The patient played basketball regularly in high school and college. The family history was reported elsewhere.⁴

Subhemophilia.—A 22-year-old male college student (W. McL.) was always in good health. At the age of 16 after circumcision, he had a slow ooze from the operative wound for nearly a week.

In the patient with subhemophilia who had had a single bleeding episode, the AHF was 33% of normal. It will be observed that there is a good correlation between the plasma AHF levels and the severity of the bleeding diathesis. The partial thromboplastin time was prolonged in patients with severe and moderate hemophilia but was normal in patients with mild hemophilia and the subhemophilia. These results were to be expected, since Langdell and associates¹ have shown that the partial thromboplastin time is normal when the plasma AHF content is at least 15%. In contrast to these results, the clotting time and prothrombin utilization tests were abnormal only in the patient with classical hemophilia. These methods appear to be less sensitive than the partial thromboplastin time in detecting a clotting defect of moderate severity.

The finding of a person with an AHF level of 33% led to the determination of plasma AHF in a large number of normal adults. Results of one such study on 47 normal subjects are shown in figure 1. AHF values are given as the nearest 10% figure. Over a threefold difference from the lowest to the highest value (50 to 170%)

CLOTTING TESTS IN HEMOPHILIA

Clotting tests on the patients with hemophilia or subhemophilia are given in table 1. These patients were selected to illustrate (1) the variation in plasma AHF levels in different patients with hemophilia, and (2) the relationship between AHF levels and other laboratory tests.

Fig. 1.—Plasma antihemophilic factor (AHF) levels of 47 healthy normal adults of either sex.

The AHF assay revealed none of this clotting factor in the patient with classical hemophilia; a trace of AHF was found in the patient with moderate hemophilia; and 16% of AHF was found in the patient with mild hemo-

was observed. Periodic determination of AHF levels in the same persons showed that the antihemophilic activity of plasma remains remarkably constant and appears to be characteristic of the individual person. In the survey of normal persons, no other subjects with AHF below 50% were found; however, in a family previously reported,⁴ there were seven persons, one male and six females, with AHF levels in the range of 30 to 45%. It was found that 63% of the persons in the 30-45% range had bled excessively after operative procedures. The operative procedures included cesarean section, hysterectomy, tonsillectomy, oviduct ligation, and uterine curettage. All except two patients had occasional epistaxis and bruised easily. The bleeding from wounds was a slow ooze, and the rebleeding phenomenon occurred. From the data at hand, it appears that with stress to the hemostatic mechanism still lower AHF levels may develop in persons with low AHF levels and they become temporary bleeders. For this reason we have designated this group as subhemophilia.

HEMOPHILIOID STATES

Several hemophilia-like hemorrhagic diatheses have been recognized in the past six years. A variety of terms has been used to designate this group of congenital bleeders. Among the terms used are parahemophilia, Owren's disease, Ac-globulin deficiency, labile factor deficiency, factor 5 deficiency, congenital deficiency of

4. Graham, J. B.; McLendon, W. W., and Brinkhous, K. M.: Mild Hemophilia: An Allelic Form of the Disease, *Am. J. M. Sc.* 225: 46 (Jan.) 1953.

proaccelerin, serum prothrombin conversion accelerator (spca) deficiency, congenital hypoproconvertinemia, Christmas disease, plasma thromboplastin component (PTC) deficiency, plasma thromboplastin antecedent (PTA) deficiency, or merely a special form of hemorrhagic diathesis. There appear to be at least three, and probably four, separate clotting factors concerned in these congenital deficiencies. Much disagreement exists among workers in the field of blood clotting regarding the mechanism by which these various new clotting factors contribute to physiological thrombin formation. The varied nomenclature is in part a result of different theories that have been propounded in recent times regarding the sequence of events in the early phases of blood clotting. Until critical data are available to determine the exact biochemical reactions in which each of these factors participate, the use of a nonspecific terminology for this group of deficiency states is proposed. This terminology, along with the deficient plasma factor, is indicated in table 2. Hemophilia, because of its clinical and pathological similarity to these diseases, is included. Revisions of the list can be made as new facts are established. A brief summary of the more pertinent characteristics of these newly recognized hemorrhagic diseases is given below. A clinical abstract illustrates each type of disease.

Hemophilioid State A (Parahemophilia).—Parahemophilia was first clearly described by Owren in 1947.⁵ Since then at least 16 well-documented cases have been reported. Epistaxis and dermal ecchymoses, without hemarthroses, are the most frequent hemorrhagic manifestations. Either sex may be involved. Laboratory data indicate that bleeding time, clot retraction and platelet counts are within the limits of normal. The clotting time may be prolonged to 30 or 60 minutes (normal 9 to 12 minutes). The prothrombin time is long, but plasma prothrombin levels determined by the modified two stage procedure are normal. Prothrombin consumption tests show slow utilization of prothrombin in clotting blood. The factor in normal plasma that corrects the deficiency is a globulin, since it is precipitated between 25 and 50% saturation with ammonium sulfate. It is not adsorbed onto barium sulfate and disappears rapidly on aging of plasma. The disease may occur sporadically but usually there is a positive family history, with occurrence of a similar bleeding tendency in siblings, one parent, aunts, uncles, cousins, or more distantly related relatives.

The patient (D. H.), a 3-year-old girl, appeared well until 6 months old, when a hematoma developed at the site of a needle puncture wound. Later, after a fall in which she bit her tongue, bleeding and a severe hematoma developed. Blood transfusions were followed by prompt hemostasis. There were no known bleeders in the family. Prothrombin (two stage method) was 105%, and the AHF value was 78%.

Hemophilioid State B.—The hemorrhagic diathesis, hemophilioid state B, was described by Alexander and co-workers in 1951.⁶ Only four other cases have been reported since then, aside from the case referred to below. Epistaxis and dermal ecchymoses are the most common hemorrhagic manifestations. Hematuria, melena, and hemarthrosis have also been described. The clotting time

may be somewhat prolonged; the highest value reported is 20 minutes. In the severest case prothrombin utilization was impaired. The prothrombin time is prolonged, but prothrombin determined by a modified two-stage procedure is normal. The factor that corrects this defect is removed from normal plasma by the common adsorbents for prothrombin, including barium sulfate. The plasma factor is thought to be converted to an active form (e. g., serum prothrombin conversion accelerator) during clotting. It occurs in both sexes and in siblings. The mother may be affected.

The patient (R. S.), a 32-year-old man, had had bleeding episodes since birth. There was excessive bleeding for two days from the ligated umbilical cord. There were repeated episodes of epistaxis, hematuria, and melena. Subcutaneous hemorrhages were frequent. His joints were swollen (hemarthrosis?). Other relatives were subject to free bleeding, but were not tested. The clotting time was 20 minutes. Prothrombin (two stage

TABLE 2.—Hemophilia and Hemophilioid States, with Associated Clotting Factor Deficiency

Hemorrhagic Disease	Deficient Factor	Probable Synonyms for Deficient Factor
Hemophilia	Antihemophilic factor (AHF)	Antihemophilic globulin (AHG) Thromboplastinogen Thromboplastic plasma component (TPC)
Hemophilioid state A	Accelerator globulin (AcG)	Labile factor Factor 5 Accelerin
Hemophilioid state B	Serum accelerator factor (SAF)	Serum prothrombin conversion accelerator (spca) Convertin Factor 7 Stable factor Co-thromboplastin (Mann)

Hemophilioid state D	Plasma thromboplastin antecedent (PTA)	

method) was 100%, and AHF was 180%. The prothrombin utilization test (two stage) was normal.

Hemophilioid State C.—Aggeler and associates carefully studied hemophilioid state C in 1952.⁷ Fourteen additional cases have been reported in the last year. The commonest hemorrhagic manifestations are epistaxis, dermal ecchymoses, and hemarthroses. The bleeding time and clot retraction tests and platelet counts are within normal limits. The clotting time is prolonged; it may be delayed for only a few minutes or for several hours. Plasma prothrombin is normal and the prothrombin time is normal. The factor in normal plasma that corrects the defect is adsorbed along with prothrombin onto many adsorbents, including barium sulfate. The factor is precipitated by 45 to 50% saturation of normal plasma with

ammonium sulfate. The disease has been described only in males, except for the patient indicated below. Most cases have occurred in families in which the transmission appears to be sex-linked, as in hemophilia.⁷ Several sporadic cases have been described.

The patient (V. M.), a 49-year-old housewife, had had a bleeding tendency since childhood. She bruised easily throughout childhood, and epistaxes were frequent. Tonsillectomy during childhood was not followed by excessive bleeding; however, uterine bleeding was excessive after each of three deliveries. Excessive bleeding also occurred after tooth extractions. In 1953, after a thyroidectomy, there was extensive postoperative hemorrhage that was controlled by blood transfusions. Two sons were bleeders; one had repeated hemarthroses and was crippled. The clotting time was 12 minutes. The

The corrective factor in normal plasma appears to be adsorbed onto barium sulfate. The three patients described have been in one family—a man and his two nieces.

The patient (B. Y.), a 29-year-old housewife, had had a mild bleeding tendency since childhood. It was observed particularly after tooth extractions. The family history, as well as other data on this patient, was described earlier by Rosenthal.⁸ The clotting time was 15 minutes. Prothrombin (two stage) was 96% of normal, and AHF was 142%.

CLOTTING TESTS IN THE HEMOPHILIOID STATES

In general, the recognition of the various members of the hemophilioid group as separate hemorrhagic states has been dependent on extensive laboratory studies of the blood. These studies included negative findings, such as normal fibrinogen, prothrombin, clotting inhibitor, and platelet numbers, coupled with the positive finding of delayed conversion of prothrombin to thrombin. The latter was indicated by (1) a long prothrombin time, in which the plasma clotted relatively slowly in spite of normal prothrombin levels and the presence of potent thromboplastin, (2) slow disappearance of prothrombin from clotting blood in prothrombin utilization or consumption tests, or (3) slow evolution of thrombin in the two stage prothrombin assay. Further localization of the clotting defect was dependent on special studies. In the main these consisted in determining the effectiveness of normal plasma and serum fractions, and of plasmas with known deficiencies, on the clotting defect under study. Clear-cut corrective or noncorrective action helped to categorize the nature of the hemorrhagic diathesis.

An effort was made to find a pattern of simple tests by which each disease in the hemophilia-hemophilioid group could be identified. Comparative clotting studies were done on the four patients mentioned above, each with a different hemophilioid state, and on the classical hemophiliac (T. W. T.). The clotting studies consisted of prothrombin time and partial thromboplastin time determinations. The results are shown in figure 2. In section 1 of the figure it will be noted that the partial thromboplastin time is prolonged in all five of the patients in this group, whereas the prothrombin time is prolonged in only hemophilioid states A and B. In section 2 of the figure it is seen that, on mixing pairs of plasmas in all combinations, the prolonged clotting times noted in section 1 of the figure become normal. The mutually corrective action on the clotting defect of these plasmas strongly supports the idea that each of the patients had a deficiency of a separate clotting factor. In section 3 of the figure are given the results of the two clotting tests after adding to the patient's plasma, normal plasma adsorbed with barium sulfate. The adsorbed plasma contains three important clotting factors, fibrinogen, AHF, and the factor missing in hemophilioid state A, but it lacks prothrombin and the three factors missing in hemophilioid states B, C, and D. As would be expected, the partial thromboplastin time becomes normal in hemophilia and hemophilioid state A after fortification of the patient's plasma with barium-sulfate-treated normal plasma but remains unchanged in hemophilioid states

Fig. 2.—Prothrombin times and partial thromboplastin times on oxalated plasmas of patients with hemophilia or a hemophilioid disease: (1) standard clotting tests with 0.1 ml. plasma, 0.1 ml. thromboplastin, and 0.1 ml. of 0.02 M calcium chloride were used; (2) 0.1 ml. of plasma mixture consisting of equal parts, as indicated, used in the standard clotting tests; and (3) 0.1 ml. of plasma mixture consisting of equal parts of plasma indicated and barium-sulfate-treated normal plasma, used in the standard clotting tests.

prothrombin (two stage) was 100%, and AHF was 93%. Prothrombin utilization was impaired, with 56% prothrombin remaining in the serum at two hours.

Hemophilioid State D.—Only three cases of hemophilioid state D have been described, all by Rosenthal in 1953.⁸ Excessive bleeding after tooth extraction is the commonest hemorrhagic manifestation. Prothrombin levels by the two stage method, prothrombin time, bleeding time, clot retraction and platelet count are all normal. The clotting time is somewhat prolonged (15 to 29 minutes). The prothrombin consumption test is prolonged.

8. Rosenthal, R. L.; Dreskin, O. H., and Rosenthal, N.: New Hemophilia-Like Disease Caused by Deficiency of a Third Plasma Thromboplastin Factor, *Proc. Soc. Exper. Biol. & Med.* 82: 171 (Jan.) 1953.

B, C, and D. The prolonged prothrombin time after fortification becomes normal in hemophilioid state A but not in state B.

PROCEDURE FOR DIAGNOSIS

The data presented in figure 2 provide the basis of a relatively simple schema for differentiating the bleeding diatheses that belong to the hemophilia and hemophilioid group. The procedure consists basically of two tests, the partial thromboplastin time and the prothrombin time. Each test is done on the patient's plasma alone, as well as on the patient's plasma fortified with equal volumes of fresh normal barium-sulfate-treated plasma. Table 3 shows the distribution of results with this group of patients. The patients fall into four main groups: (1) hemophilia, (2) hemophilioid state A, (3) hemophilioid state B, and (4) hemophilioid states C and D. The latter two states are not differentiated in this procedure.

This procedure has the limitation that mild deficiencies may not be detected. Thus, in very mild hemophilia, all of the tests are negative. In mild cases, more complicated tests designed to quantify the degree of the clotting factor deficiency are necessary. Also, in the differentiation of the various disease states, this procedure may not be adequate; for example, a two stage prothrombin determination, made after addition of the B factor, is needed to distinguish hemophilioid state B from hypoprothrombinemia. In case the plasma fits into the fourth category, either type C or type D hemophilioid state may be present. A presumptive diagnosis may be made by doing partial thromboplastin times on the patient's plasma after mixing with known type C and type D plasmas, instead of with barium-sulfate-adsorbed plasmas.

INHERITANCE OF HEMOPHILIA AND HEMOPHILIOID STATES

The inheritance of hemophilia is the best understood of this group of hemorrhagic diseases. Classical hemophilia was one of the first diseases to be recognized in modern times as being inherited as a sex-linked recessive characteristic. With rare exceptions, the disease is seen only in males. Genetic theory attributes the disease in the male to the presence of the recessive gene h on the unpaired portion of X-chromosome. The normal male has the dominant gene H in the same chromosomal locus. It is thus assumed that with the gene H the body is able to produce normal amounts of plasma AHF, but with the gene h this ability is lost. In the female conductors, both genes H and h are present, one on each of the X-chromosomes; these heterozygotes have normal plasma AHF levels.

In hemophilia, there are five possible crosses: (1) heterozygous female ($X^H X^h$) and normal male ($X^H Y$), the usual cross in hemophilia; (2) normal female ($X^H X^H$) and hemophilic male ($X^h Y$), an increasingly frequent cross as more hemophiliacs reach maturity; (3) heterozygous female ($X^H X^h$) and hemophilic male ($X^h Y$), an extremely rare cross in human genetics, and from which a hemophilic female may issue; (4) hemophiliac female ($X^h X^h$) and normal male ($X^H Y$); and (5) hemophilic female ($X^h X^h$) and hemophilic male ($X^h Y$). Only in canine hemophilia have all of the pos-

sible crosses been tested.⁹ All of the combinations gave progeny exactly as the theory of sex-linked inheritance predicts, including the above-mentioned cross 4, which has not yet been reported in detail.

The study of families with either mild hemophilia or the subhemophiliac trait has added to the knowledge of the inheritance of this disease. In one family with the mildest form of hemophilia,⁴ the affected males rarely bled excessively, and their plasma AHF level was in the range of 12 to 22%. The constancy of the disease and the AHF levels in the affected individuals led to the postulation that they had an allelomorphic form of hemophilia, due to an allele h^m , distinct from h , which is responsible for classical hemophilia. The allele h^m , then, permits production of AHF, but not in amounts sufficient for effective hemostasis.

In the case of the subhemophiliac (W. M.), his four siblings had AHF levels in the narrow range of 57 to 69%. This is in marked contrast to the spread in AHF levels in a group of randomly selected normal adults (fig. 1). Similar results were found in other families in which various members had roughly the same AHF levels. It appears that there may be a series of isoalleles,

TABLE 3.—Schema for Differentiation of Hemophilia and Hemophilioid States

Presumptive Diagnosis	Prothrombin Time		Partial Thromboplastin Time	
	Plasma	Fortified Plasma*	Plasma	Fortified Plasma*
Hemophilia	Normal	Normal	Prolonged	Normal
Hemophilioid state A	Prolonged	Normal	Prolonged	Normal
Hemophilioid state B	Prolonged	Prolonged	Prolonged	Prolonged
Hemophilioid state C or D	Normal	Normal	Prolonged	Prolonged

* Prior to the test the patient's plasma was mixed with equal parts of fresh normal plasma treated with barium sulfate.

$H, H', H'', \dots$, each one of which is associated with a characteristic level of plasma AHF. This series of alleles may be a continuous one, and would account for the range of normal AHF levels, as well as the AHF levels characteristic of subhemophilia, mild hemophilia and the more severe forms of the disease. The series may be represented as $H, H', H'', \dots, h^m, h^m, h$.

The clear recognition of the hemophilioid states has been relatively recent, and genetic studies in most cases are fragmentary. In hemophilioid state A, the disease has been observed in both sexes and has been transmitted by both sexes, either affected or unaffected. While the transmission appears to be autosomal in type, it is not clear if it is recessive or dominant with variable penetrance.¹⁰ In hemophilioid state B the disease occurs in both sexes. In the two families best studied, transmission through an affected mother suggests that it may be an autosomal dominant. The inheritance of hemophilioid state C is very similar to that in true hemophilia.

9. Brinkhous, K. M.; Graham, J. B.; Penick, G. D., and Langdell, R. D.: Studies on Canine Hemophilia, Transactions of Fourth Conference on Blood Clotting and Allied Problems, New York, Josiah Macy, Jr. Foundation, 1951, p. 51.

10. Brink, A. J., and Kingsley, C. S.: A Familial Disorder of Blood Coagulation Due to Deficiency of the Labile Factor, Quart. J. Med. 45: 19 (Jan.) 1952.

All of the cases have been in males, except for one in the woman who was reported on in this paper. This patient may be a homozygote or a heterozygote with a high degree of expressivity of the affected gene. Koller and associates¹¹ have reported a family that appears to belong to this category. While only males had the disease, several mothers of the patients had a minimal clotting defect as determined by the prothrombin consumption test. This suggests that although the disease is sex-linked, the clotting defect may be manifest in the heterozygotes. In hemophilioid state D, only one family has been reported.

COMMENT

Undoubtedly some patients reported as hemophiliacs in the past would, if studied today, be placed in the group of hemophilioid states. It seems that in the light of modern knowledge, the term hemophilia should be reserved for the congenital disease in which there is a deficiency in a plasma protein, not adsorbed on barium sulfate, which is precipitated from plasma by 30% saturation with ammonium sulfate. This deficiency results in a series of characteristic clotting tests if the disease is severe or in a low AHF by assay if the disease is mild. "Cross-matching" the plasmas of suspected hemophiliacs with well-established hemophiliacs is a valuable procedure in diagnosis, particularly in the milder cases. By both genetic and chemical criteria, our colony of bleeder dogs are hemophiliacs.⁹ These animals have served as a standard of reference for many cases of human hemophilia.

It is of interest that most studies designed to detect a clotting abnormality in the female conductors of classical hemophilia have been negative. Occasional positive reports have been made, however.¹² In hemophilioid state C, on the other hand, the females appear to exhibit a latent clotting defect, or even a hemorrhagic diathesis. The hemophilic families, reported on in the past, in which female transmitters were observed to have a mild clotting defect may actually have had hemophilioid state C, rather than true hemophilia.

Many cases in the hemophilioid group may have been considered to be hypoprothrombinemia, especially in states A and B. In both of these states, the prothrombin time is long. Several years ago a long prothrombin time in itself was considered by some workers as indicative of a lowered plasma prothrombin. It is now known that the prothrombin time is dependent as much on other factors, particularly the B factor, as on prothrombin.¹³ The case of hypoprothrombinemia reported by Rhoads and Fitz-Hugh in 1941^{13a} was probably an example of hemophilioid state A, since the prolonged prothrombin time was corrected by prothrombin-free plasma.

SUMMARY

Hemophilia varies from mild to severe in its hemorrhagic manifestations. In severe classical hemophilia no antihemophilic factor (AHF) can be detected in the plasma, whereas in the mildest form of the disease there may be as much as 20% AHF. A simple clotting test, the partial thromboplastin time, furnishes a sensitive index of the clotting defect in all except the mildest cases of this disease. Normally, there is over a threefold range of plasma AHF, 50 to 170%. A given person appears to have a constant and characteristic level of this clotting factor. A group of persons were found who had AHF values intermediate between normal and hemophilic, 30 to 45%. With stress to the hemostatic mechanism, such as occurs postoperatively, these persons may suffer from transient bleeding (subhemophilia). Data now available suggest that the AHF level is determined by the existence of a series of isoalleles (H , H' , H'' , . . .), the allele in a pair that is related to the higher AHF level being dominant. The milder forms of hemophilia also appear to be allelic. The allelic series may be designated: H , H' , H'' , . . . h^m , h .

At least four separate hemophilia-like hemorrhagic diseases have been described in the past few years. A nonspecific terminology, hemophilioid states A, B, C, and D, is proposed for these diseases, pending clarification of the exact clotting anomaly in each state. All of the hemophilioid states resemble hemophilia in that they have impaired conversion of prothrombin to thrombin and a prolonged partial thromboplastin time. A simple schema, based on partial thromboplastin time and prothrombin time determinations, is outlined for the differential diagnosis of hemophilia and the hemophilioid states.

Smallpox.—Although usually considered to be an extremely infectious disease, smallpox does not have the epidemic potential of influenza or even of chickenpox. In the records of recent outbreaks, spread has usually been traced to direct contact between cases. It is true that spread may sometimes be indirect, for example, through infected bed linen. . . . The virus may survive for months or even years outside the body. . . . Epidemiological evidence suggests that most cases of smallpox are not infectious from the onset of illness but become so at the time of appearance of the skin eruption. This view was strongly held by Ricketts and is supported by recent observations. For example, in the Glasgow outbreak of variola major in 1949, individuals were infected from the first undiagnosed case and many of them were not detected and isolated until the appearance of the rash; yet none of these gave rise to further clinical cases although vaccination of contacts had not been carried out at this time. At the time the eruption occurs there is a large amount of virus in the lower layer of the skin epidermis, but, because of the impermeable nature of this tissue, virus is not shed into the environment until the rupture of vesicles and pustules at a later stage. In the mouth and pharynx, however, this protective layer is absent and lesions break down early and thus rapidly render the saliva infective. We have been unable to demonstrate any inhibitory effect on variola virus of saliva from unvaccinated or recently vaccinated persons; and our attempts to demonstrate variola virus in the mouth during the first two days of the pre-eruptive fever have so far been unsuccessful. In acute cases of purpura variolosa, however, where bleeding may occur under the skin from mucous membranes soon after the onset of illness, the patient may be infectious throughout the febrile period. THE MEDICAL PREPARATION OF A MEDICOLEGAL CASE

THE PHYSICIAN'S VIEWPOINT

Theodore J. Curphey, M.D., Hempstead, N. Y.

When one recognizes that, in the future, the greatest contributions in the field of medicine are likely to lie in that area relating medicine with the social problems of the community, it becomes at once obvious that forensic medicine by its very medicosocial nature represents an area that is ripe for development at this time. Much of the expert testimony presented in courts in this country at this time is of decidedly low quality, reflecting no credit to either medicine or the law. Indeed, by the very nature of the methods by which this evidence is gathered and presented, such expert testimony frequently works against the best interests of justice. A conference of this kind, therefore, serves a most useful purpose, in that it pinpoints the problem and provides an opportunity for its analysis and the development of ideas leading to its improvement. I believe, therefore, that the example that you have set today in the development of this program is one that is worthy of emulation by the higher centers of learning in the rest of the country, and I do hope that its influence will become widespread. If by good fortune this does occur, and the medical schools are stimulated thereby, one sincerely hopes not only that the subject will be taught in the didactic sense, as is true for the most part at this time, but that attempts will be made to give the undergraduate medical student what might be called "clinical" experience in the law courts, whereby opportunity is provided him to see a court in action with the testimony of witnesses, technical, expert, and otherwise.

PRELIMINARY CONSIDERATIONS

In discussing now the medical preparation of a medicolegal case, let me point out that medicolegal work demands a distinctly different mental attitude on the part of the physician from that applicable to the general care of patients. For example, in medical practice the physician has ample time to observe the daily changes in the disease of his patient and by means of certain diagnostic aids is able finally to arrive at a diagnosis through a succession of observations and on this basis to administer the indicated treatment. Compare this now with the doctor in court who is called on to render expert medical testimony. In contrast to the case in his medical practice where he has had many hospital or patient days to formulate his final opinion, on the witness stand the doctor has only one day in court. In order, therefore, to utilize this to its fullest advantage, he must come adequately prepared to testify on the basis of a full knowledge of the facts, coupled with sufficient medical experience in the particular field to enable him to render a final opinion that will withstand the rigors of cross examination by the opposing attorney and thereby carry full conviction in the eyes of the jury. To do this efficiently entails a good deal of preliminary preparation prior to testifying as well as some knowledge of court procedure. The basic elements involved in such preparation, first on the part

of the physician and then in conjunction with the attorney for his side, constitute the basis of my presentation this afternoon. At the outset, let me say that my succeeding remarks must not be construed to represent a fixed pattern of preparation in every medicolegal case, for obviously cases differ as to the importance of the problems involved, with the consequent need for varying degrees of effort, time, and preparation.

Assume, then, that the medical expert on the basis of a request from a lawyer decides to take a case. His first responsibility prior to its preparation is to review the working data presented by the lawyer to him. This cannot and should not be done by the only too common practice of a single telephone conversation. Rather, it is necessary for the lawyer and the doctor to meet in person and to study with some care the information currently available. Parenthetically, I might add that it is fair to say that much of the medical information initially supplied by the lawyer lacks many details that are necessary for a full and proper medical evaluation of the problem. After this personal contact and the review of the evidence, the medical expert has a choice of one of two approaches, depending on the importance of the case. Thus, if he feels that there are sufficient medical facts available, even although they are admittedly incomplete, and that these facts will be strong enough to provide him with the basis for sound testimony on the witness stand, then he will accordingly prepare his testimony along these lines. If, on the other hand, the case is of great importance, or the medical facts are scant, it becomes necessary for the medical man to so inform the lawyer, emphasizing at the same time the need to have an investigator seek to obtain further medical facts, if such be available. After the collection of these, the physician then prepares his case for testimony.

At this initial interview between the lawyer and the doctor, it frequently becomes necessary for the latter, after a study of the medical data on the case, to point out that, because of the very nature of the problem, there is not at the moment adequate current medical knowledge that would enable him to express a positive opinion on the basis of the evidence, as sound and complete as it is. For example, if, in a person working in an environment in which he is continually exposed to radioactive material, a marked change develops in the blood leading to anemia and death and if at autopsy the presence among other things of a level of radioactive material is shown in the bones above that normally accepted as the limit of tolerance, then there is sound reason for the opinion that death was due to his occupation. On the other hand, if another and perhaps older person working

in a different environment dies suddenly and at autopsy certain changes are shown in his coronary vessels, such as thrombosis or occlusion by arteriosclerosis, then there are sound grounds for a difference in medical opinion as to whether his occupation was the immediate cause of death. It is in this latter twilight zone of current medical knowledge that many of these medicolegal cases lie. It behooves the medical expert to inform the lawyer that such is the case, and it is further his responsibility to acquaint the lawyer with the views contrary to the opinion he is prepared to express. This, besides helping the lawyer in the preparation of his case, also provides him with the opportunity for deciding whether the medical expert with such views is the man that he would have represent his side in court.

In general then, the first interview between the lawyer and the doctor is a most important single step in the medical preparation of a case, as it gives the doctor the opportunity to decide on the merits of the medicolegal facts and whether he would desire to testify for the lawyer on the facts submitted. It is at this interview also that the lawyer can decide by his estimate of the doctor's approach to the problem whether he is likely to be a good advocate for his cause. Like the juror, the lawyer is not expected to know a great deal about medicine, but, by virtue of his experience with people, he has an opportunity to observe the workings of the doctor's mind in his approach to the problem confronting him. I would advise any lawyer approaching such an interview to study the doctor's reactions as to the evidence supplied him. If he appears to be too ready to accept all the medical facts as supplied and conveys the idea that the case is a "cinch" and that he should have no difficulty winning it, then the lawyer should beware of such a superficial approach, as it is probable that the doctor in question is not likely to give the matter more than superficial attention either in the course of preparation or in testimony in court. A personal discussion of this sort also provides the lawyer an excellent opportunity for estimating the objectivity and poise of the physician whom he contemplates engaging to present his medical side.

Here, too, a word might be said to the physician in respect to the initial contact with the lawyer in medicolegal matters. Many lawyers have told me of the difficulties they have in getting busy physicians to set aside sufficient time for the purpose of discussing in detail the medicolegal aspects of a proposed law suit. The serious lawyer who prides himself on the proper preparation of all the aspects of his case complains bitterly of the unwillingness of the busy physician to devote enough time and thought to study the data prior to developing a case for presentation to the courts. Frequently this works a distinct hardship on the lawyer and certainly on his client, because often it is this physician alone who possesses such evidence in the case as to offer a good guarantee of a favorable verdict to the client. The responsibility of such a medical man is clear, for if he has been willing to treat the case and if such a case is later subject to litigation, then his professional responsibility is to see the case through to trial. With these preliminary remarks, let me now proceed to a discussion of certain general principles that govern medical preparation and testimony.

GENERAL PRINCIPLES GOVERNING MEDICAL PREPARATION AND TESTIMONY

The first and basic principle governing the preparation and the presentation of testimony in a medicolegal case concerns records. Because of the considered importance of this matter, for some years now in the County of Nassau and through the influence of the medical examiner's office, it has been the practice to invite a representative of the district attorney's office to meet each July with the incoming house staff of Meadowbrook Hospital, the county institution, to discuss and outline the significance of accurate medical records, especially on cases that are likely to come to court. Dealing now directly with the matter of medical testimony, it is first of all important for the expert in the course of his testimony in court to give evidence of his objectivity and lack of partisanship, even although he is being paid a fee by one side for his testimony. His acceptance of the case is proof of his conviction that there are medical merits in the claim of the side that he represents. He must also recognize that the opposing side must have certain merit in their medical facts or there would be no litigation. Appreciating this, he will do more good for his side if he shows no reluctance in admitting the validity of the opposing medical facts when under cross examination, providing they warrant it. He should do this to the same extent that he has been willing to point out the existence of this controverting medical testimony to his lawyer in the course of preparation of the case. Such action puts him and his side in a stronger position in the eyes of the jury. In so doing, the medical strength of his side should not in any way be weakened provided there has been sufficient preparation and understanding between him and his legal associate as to how such controverting medical evidence is to be handled in his redirect examination by his own lawyer.

Another principle of importance is the willingness of the medical expert to admit personal limitations in his knowledge when under cross examination. At times, this might seem to be a bitter pill to swallow for the lawyer who employs him, as he would naturally like to assume that his medical witness is the fount of all knowledge. However, I think experience has shown that the jury is frequently more impressed by the medical witness who makes no pretense at omniscience and who is willing to admit lack of personal knowledge when such exists.

Still another general principle is that of expressing oneself on medical matters in the language of the layman, and further related to the use of simple understandable language in testifying is the strict avoidance of a patronizing attitude on the part of the physician, either to the opposing lawyer in the course of cross examination or to the jury when he is called on to explain certain medical facts to them. I think it is very important for the medical witness in court to realize that he is at times viewed by the jury with a certain degree of hostility, based no doubt on the understandable human reaction of a degree of suspicion toward anyone who seems to be deliberately "speaking over one's head." Obviously most physicians do this not for the desire to impress the jury with their knowledge but rather because of the common habit of the use of medical jargon, which is frequently quite unintelligible to the layman.

These in brief are some simple principles that make for better rapport among the physician, the lawyer, and the court and that also serve to enhance the value of the medical witness in the course of his day in court. Leaving now these general ideas, I will next consider the specific steps that must be taken in the actual preparation of a medicolegal case prior to presentation of evidence in court.

STEPS IN PREPARATION OF A MEDICOLEGAL CASE

The data presented under this heading will be divided into cases that are tried in (a) the criminal, (b) the civil, and (c) the compensation courts. It should be stated that a common thread runs through the preparation of all types of medicolegal cases, namely, the need for an adequate and complete collection of the medical facts and then a detailed record of these facts for future reference. While the title of my discussion implies the preparation of the case with the lawyer for the purposes of testifying in court, let me say that, in my opinion, much greater stress should be placed on the actual collection of the medical evidence at a time even when no suspicion of a court trial exists.

Present Status of Medicolegal Procedure.—I will not attempt to express an opinion on the relative quality of the medical facts currently collected and recorded in the medicolegal field in the United States as a whole. I can, however, as a pathologist venture an opinion in that specific but fairly broad field of medicolegal work in which death occurs and where subsequently a criminal, compensation, or civil case ensues. I have no statistical facts on this matter, nor do I know how to acquire them, but I think nevertheless that it is perfectly safe to say that the number of such cases in which autopsy is performed by inexperienced physicians in this country, inexperienced in the sense of not having had special training in pathology, far outweighs those done by trained medical specialists in this field. Let me remind you that an autopsy performed in a case in which death occurred under suspicious circumstances might, if poorly handled, be indirectly the means of condemning an innocent man to death or contrariwise of freeing a criminal. So you see that in handling the medical preparation of the medicolegal case, one must get to the fundamentals of the problem, namely, the basic medical skill and experience necessary for the initial gathering of the evidence.

We must face the facts clearly. The quality of medicolegal work being done in this country comes close to the borderline of being a menace to the life, the liberty, and the substance of many of our citizens. I feel a singular delight in being able to voice this opinion before this audience, as I know full well that the state of Michigan is cognizant of its responsibilities in this field and has recently passed Senate Bill 1293 in the legislature, directed toward the abolition of the outmoded coroner system and its replacement by a medical examiner system. Here, I should like to pay a special tribute to the untiring efforts of your Dr. LeMoyne Snyder of Lansing, who has worked indefatigably during the last 17 years in an effort to obtain the passage of such a bill. At present, the bill allows the individual boards of supervisors in counties of your state to determine for themselves whether the medical examiner system shall replace the

coroner system. This modernized approach should improve greatly the quality of medical testimony in court. I cannot let this opportunity pass without emphasizing what I consider the most important legislative advance in this field, and that is the establishment of a wide legal framework for the investigation of the circumstances surrounding the deaths of persons in the community other than those suspected of being of criminal nature.

Lest I be accused of being partisan let me immediately say that, if a coroner's system operating in a community is provided with an inclusive enough legal background and if the law is administered through the functioning of physicians well-trained in pathology and forensic medicine, then the quality of medicolegal work provided in that community should not be greatly different from that rendered under the more modern type of medical examiner's system. One has only to think of the excellent activities of the coroner's system in Cleveland to recognize this. The same is equally true in other parts of the country, notably in Louisiana, where an inclusive coroner's law has been rewritten recently.

Beginning the Investigation.—Returning now to the main thread of the discourse, let me briefly consider the steps in the preparation of evidence in the first type of case, namely, a criminal case. Here one must emphasize the value of having a single medical investigator follow the case through from the actual scene of occurrence of the death to the witness stand. The information that the forensic pathologist obtains from a personal inspection at the scene of the crime is of fundamental importance. It is almost mandatory for him at the scene to record pertinent facts, such as the position of the body, the nature of the immediate physical surroundings, and the careful search for weapons, bullets, poisons, and the like. Coupled with this should be interrogation of either the witnesses to the crime or the persons in physical proximity to the location of the body at the time the police and the medical examiner arrive at the scene. An attempt should also be made to obtain photographs of the scene. This is usually done by the police, and special attention is paid to the location of the body and of important objects, by the device of special markings, markers, and the like.

An important part of this investigation is the proper identification of the deceased, with the name and address, and relationship if any of the identifying person. The removal of any portable objects that might be necessary in the investigation and that might later be used at the trial must also be carefully attended to. Such objects must be marked properly, catalogued, and placed in the safe keeping of a responsible party associated with the investigation, be it the medical examiner, the coroner, or the police. After this, the body is now in the custodial care of the forensic pathologist, and from here the chain of evidence is gradually forged. The intact preservation of this chain is something that cannot be too strongly emphasized. I believe that in many of the large jurisdictions, whether they operate under the coroner or the medical examiner it matters not, insufficient attention is paid to the preservation of this chain of evidence. I have often wondered what would happen to the expert medical witness in a major criminal case if the opposing lawyer spent

time probing into the question as to the real continuity of the evidence in respect to the handling of the investigation. Indeed, I know of an occasional case in which, because of laxity in this respect, the medical evidence was nearly upset by the simple expedient on the part of the opposing attorney of casting doubt on the proper identification of such things as organs of the diseased, improperly submitted to the toxicologist for examination. This matter is extremely important to the forensic pathologist, and he should make every effort to be certain that, from the time the body comes in to his care, until he testifies on the witness stand, he can personally vouch for lack of interference or tampering, either with the body or with the material removed therefrom at the autopsy for subsequent laboratory examinations. He must be certain on the witness stand that the opinions expressed on the materials examined represent such material coming from no other person than the dead person. In a large organization this is not always an easy matter, as the possibility of mixing or loss of specimens always exists. By setting up a system of cross checks as a general routine in the operation of his office, the forensic pathologist can easily avoid this dangerous error. For example, if the body is to be kept in the morgue overnight, it should be kept under lock and key. Organs that are removed for various laboratory examinations, including toxicologic tests, should be personally delivered to the laboratory technicians and signed for on receipt. Specimen containers must be labeled before specimens are placed in them, not after, as is often the case, and the name on the label should be checked by the pathologist before the specimen is placed in the container. Similarly, in connection with the withdrawal of blood for chlorides from the right and left sides of the heart in cases of drowning, it is important that the pathologist read carefully the labeled bottle and that the blood from the side corresponding to the label is placed in the proper bottle for subsequent chemical examination. Technicians and morgue workers are human and are subject to error. Such error can be readily avoided, however, by setting up beforehand a routine system and by carefully watching the material when it is being routed from the autopsy table to the various departments in the laboratory for examination. A further precaution should be taken, especially in the case of the organs retained in the toxicology laboratory. Such organs are likely to be kept for several days during the time that repeated determinations are being made and should be kept in a refrigerator under lock and key. If these simple precautions are observed, and if during the testimony in court any questions along these lines are raised by the opposing attorney, it places the medical expert in a favorable position in the eyes of the jury, if he can recount the custodial system by which he assures himself of accuracy of examination on material studied by him.

The Autopsy.—Space does not permit any detailed description of the methods surrounding the proper performance of a medicolegal autopsy. Suffice it to say that the emphasis on various phases of the examination will depend in large measure on the nature of the problem being investigated. I think it an unsound practice to approach any of these problems with what might be called a fixed routine. For one thing, such a routine frequently

makes the examination stereotyped and removes the natural keenness of interest that should be present when one handles the problem as an individual matter. Despite all this, there are certain minimal essentials that must be observed in each case. One of these deals with the examination of the clothing while still in place on the body, with the proper and detailed recording of bullet holes, powder marks, knife slashes in the fabric, and the presence of any foreign or extraneous material on the garments. All these matters must be recorded in detail in writing for future reference and for correlation with the rest of the evidence gathered at the autopsy, at the scene, and through the questioning of witnesses by the district attorney's office and the police.

Similarly, in the performance of the autopsy, great emphasis should be placed on the importance of a detailed external description of the body, with pertinent and detailed notes on the nature of the various wounds and skin injuries. Special attention should be paid to the head, especially in the cases of males with abundant hair or in females, as frequently serious head injuries might easily be missed, because of the absence of any readily visualized external laceration or injury to the scalp. It is well to remember also that the head should be opened, even if there are no immediate external indications, as frequently in the course of this routine step, evidence of definite injury to the bones of the skull and to the brain is encountered, sometimes with little or no evident injury to the external surfaces of the soft tissues of the region. It is well to remember in connection with the external examination of the body, too, that the findings described thereon are more readily appreciated by the jury because of the ease with which they can visualize these changes, in contrast to the difficulties they face when a pathologist is testifying to the presence of internal injuries to the various organs.

This attention to detail in the external examination of the body cannot be overemphasized, especially seeing that it is in sharp contrast to the general approach of the hospital pathologist, whose major concern in the routine autopsy lies with the changes noted in the internal organs. The danger, therefore, is that the hospital pathologist in his limited experience with forensic cases is likely to minimize the significance of the external findings and frequently to spend greater time than is necessary in minute detailed description of organ changes internally that really have little bearing on the case in question.

After having gathered all the necessary information from the performance of the autopsy and the preservation of specimen material for future laboratory examination, all the facts obtained from the post mortem must be put in writing, preferably at the time that the autopsy is being performed rather than at some later date. In this connection, it is important that while the autopsy is in progress a record be kept of the persons who are in attendance in the room. A practical point in this connection is to discourage the presence of any person, medical or otherwise, who has no direct connection or responsibility in the case. I know from personal experience of an occasional instance in which a medical man who casually observed an autopsy and as casually made an erroneous,

statement to the family relative to the findings was unwittingly the cause of exhumation for reexamination of the body after autopsy had been performed.

With the completion of the autopsy, it must not for a moment be thought that in every instance the pathologist now has a final answer as to the cause of death. I think this is a fundamental difference between the approach of the forensic pathologist and that of the coroner's physician. The latter, by virtue of inexperience, often feels that he is bound to supply an immediate answer as to the cause of death after the coroner's autopsy. He does this at great professional peril to himself and certainly to the detriment of the scientific investigation of the facts. One should always remember that the gross examination of the body at autopsy is frequently the starting point for a series of secondary investigations along various laboratory lines, which ultimately provide the means by which the final opinion is reached. Often the coroner's physician, possessing neither the experience in the field nor the technical facilities to conduct these investigations, finds it necessary to supply an answer on the spot. You can readily judge for yourselves how inaccurate such ill-founded medical opinions are likely to be. One of the greatest dangers lies in the too ready "off the cuff" opinion expressed by the forensic pathologist or the coroner's physician at the height of the investigation, when the reporters and the police are at fever heat and when the pathologist feels a hankering for publicity, thus frequently bartering away his good medical reputation for a headline in the morning's paper. If he is a sound medicolegal investigator, he will forego the temptation of immediate "on-the-spot" publicity, in favor of a more secure medical opinion that he later can defend on the witness stand.

Final Preparation.—With the final gathering of all the threads of evidence necessary for weaving the pattern of the final conclusion, the forensic pathologist is now able to appraise various features of the case and in so doing to arrive at an opinion that is much more likely to be objective. He must be extremely cautious in coming to any conclusion that by direction or inference will carry great evidential weight in the final trial, unless he is certain that the weight of the gathered evidence will amply substantiate this conclusion.

Another point should be emphasized in connection with the preparation of his final opinion. He might find from later study of his autopsy findings certain discrepancies that need clarifying. Such clarification should be sought for by a review of his medical facts and by conferences with the police and with any other experts who might be in a position to supply him with the answer. This is especially true in the field of ballistics where paths of bullets are frequently erratic and where it takes an expert to help the forensic pathologist in their interpretation. In this matter of seeking aid and advice from collateral investigators, the forensic pathologist should have no hesitation in admitting his lack of knowledge in any field during the investigation and should show a willingness to discuss and be advised on these matters by suitable experts. It is only by this joint approach that all the facts can be gathered and the evidence clearly defined for trial. When all these various avenues of fact collecting have been exhausted and the final opinion

arrived at, the forensic pathologist has still another and equally important function to perform in the preparation of his case, namely, that of conferring with the district attorney's office preparatory to going to trial. This, incidentally, is one of the weak spots in many jurisdictions, either because of the unwillingness of the pathologist to devote enough time to discussion with the district attorney's office or even perhaps from a disinclination on the part of the district attorney's office to cultivate a close liaison for this very purpose. In Nassau County since the inception of the medical examiner's office in 1938, it has been the fixed practice, except in obvious cases needing little consultation, for the medical examiner and the district attorney's office to meet formally for a review and a correlation of the medical and legal evidence. These reviews frequently take the form of an anatomic demonstration with the use of a skeleton to demonstrate the paths of bullets, knife wounds, blunt force injuries, and the like.

At these joint sessions a broad plan of presentation of the medical facts is evolved. The strong points in the medical evidence are emphasized, and the weak points are also brought under discussion. At times, considerable emphasis is placed on these weak points, because they might well be the basis for the defense. Various probabilities along these opposing lines are discussed, and the trial attorney is advised as to how to bring out favorable medical evidence, and suggestions are offered as to how he might handle the controverting medical testimony. Frequently too, the actual line of questioning is developed through these conferences. All these interviews necessarily take time and effort and obviously need not be undertaken in every case. There are, however, cases in which no regard should be paid to the amount of time involved, whether it be on the part of the physician or on the part of the district attorney, because of the issues at stake. One basic necessity for success is an amicable working arrangement between the district attorney's office and the medical examiner or coroner. In this pretrial stage there must be a free interchange of ideas and a frank admission of the weaknesses of the case as well as an evaluation as to where the main strength in the evidence lies. Speaking from the medical side, I can say that experience has shown that these contacts are most valuable to the physician, as he attains a better insight into the workings of the law and he hopes that his contribution is such that it makes his problems more understandable by his legal associates in the case.

If instances should arise in which the medical expert in the course of pretrial preparation with the legal team senses that it is the desire of the latter either to have the physician shade his opinion in favor of their side, or worse still, to omit from testimony important medical facts that are likely to be damaging to their case, the physician must hold his ground. His interests obviously are not those of helping the prosecution to set or maintain a high percentage of convictions or in assisting the defense through incomplete or "shaded" medical evidence to obtain an acquittal. Rather is it his professional responsibility to maintain a nonpartisan attitude, even though he might be functioning as a paid official in the role of coroner's physician or medical examiner. Fur-

thermore, he should see to it, more especially in criminal cases, that all the medical facts developed in the case be put in evidence, so as to insure their use as readily by the defense as by the prosecution. Fortunately, in many jurisdictions, this right to safeguard the defendant's interest is well handled by the expedient of supplying the defense with a full transcript of the record of the medical examiner's report.

PREPARATION OF TESTIMONY IN CIVIL CASES

The medical preparation of a civil case if such involves a death obviously follows the same principles outlined above. Apart from this type of case, the pathologist is frequently called to testify on causal relationship between some alleged injury and some subsequent medical condition, the commonest of which is cancer. The preparation for this type of case follows the general pattern. The physician should obtain all the past and present medical data that center around the injury and the subsequent course of events. He should first seek to verify their authenticity and their completeness, by means of review of the medical records dealing with the nature of the injury, the location, the duration, and the response to treatment. If such a review establishes the existence of missing links in the chain of evidence, this should be pointed out to the lawyer and suggestions given as to how and where this missing evidence might be found, as, for example, by investigation of the hospital records, on the various occasions of hospitalization both before and after the alleged injury. Conceivably some will raise the question as to the need for such elaborate investigative efforts. Let me say that, if the case is worth taking to trial, it is worth adequate preparation. More time and money spent on good investigative work often means more favorable verdicts, with the obviation of delay and postponements for purposes of obtaining further evidence that should have been available in the first place. The late Dr. Ewing of Cornell University medical school, a great medicolegal expert, used to say that more cases could be won if only more time and money were spent on investigation and less on testimony of medical experts! Furthermore, these investigations along medical lines are best conducted under the advice and guidance of a medical man rather than under a lawyer, as is frequently the case.

In these civil suits, if, after all the medical facts are assembled, sifted, and related and a conclusion arrived at, it is the opinion of the medicolegal expert that the evidence does not provide a fair chance of a favorable verdict, the legal advisor should be so informed with the reasons for such an opinion. On the basis of this, frequently he will attempt a settlement out of court.

PREPARATION OF TESTIMONY ON WORKMEN'S COMPENSATION CASES

At the outset, let me say that the experience in the matter of preparation and testimony in this type of case has been that entirely too little effort is expended by either the lawyer or the doctor on the individual problem. Frequently, the medicolegal expert is provided by telephone or in the corridor of the court with a few sketchy facts and by means of a hypothetical question is asked to express an expert opinion. The referee, ad-

ministering an admittedly generously written law, frequently rules in favor of the worker in the face of medical evidence that, if it had been properly prepared and presented, might well have led to a different finding. The result is that the employer, in the state of New York at any rate, is being forced more and more to assume responsibility for disability and death claims that on their true medical merits lack any clear-cut foundation in fact. This is especially true in cases in which diseases of the heart are concerned, as well as in proved cases of cancer, in which a single trauma allegedly occurs and in which causal relationship is postulated.

It is obviously the duty of the medicolegal expert to see that the worker's interest is protected in keeping with the spirit and the letter of the workmen's compensation law, but, if his testimony is to be of value to the court, he must be certain that his opinion is based on a true knowledge of all the medical facts in the case, including even those that might not appear to have any immediate association with the claim. This has to do especially with the past medical history of the claimant, as frequently this knowledge alone is sufficient to invalidate the claim, particularly in certain types of bodily injury cases in which such a study reveals that the symptoms allegedly related to the injury frequently antedate the time of the alleged injury, as can be easily substantiated by records from hospitals or physicians previously attending the patient.

In this type of case, one of the most important facets is the sequence of time; for example, if it is claimed that a certain injury to the testicle is the cause of cancer of the organ and if a roentgenogram of the chest taken within a week after the injury reveals metastatic seeding of the disease in the lung, there is prima-facie evidence that the cancer antedated the injury. Similar evidence might be available at times through x-ray study in claims in which cancer of the bone is presumed to be the result of a single injury. The moral here is that any compensation case involving bodily injury should be promptly and completely studied, and such study must include x-ray examination, both of the part injured and of such other body areas as are indicated by the medical examination.

In the case of death claims in compensation court, the medicolegal expert must examine carefully the autopsy findings and should attempt to correlate the clinical evidence with these findings for the purpose of determining causal relationship. He should also attempt to evaluate the accuracy of the data gathered by the lay investigators, in respect to the credibility of the statements of witnesses to the accident or injury, keeping in mind the frequency of sharply conflicting statements of witnesses as to time and location and their estimate of the effect of injury on the claimant. A further aid to the expert witness is a study of the stenographic records of previous hearings on the case, seeking discrepancies in the medical aspects of the recorded testimony.

When all this material has been analyzed and digested and an opinion reached, the expert is now in a position to discuss the aspects of the case with the lawyer and can offer advice as to the merits of the claim leading either to a settlement out of court or to a hearing.

SUMMARY

The preparation and testimony in a medicolegal case from the point of view of the physician is a matter that should not be undertaken lightly. When he is invited to testify, he must be certain that his particular experience warrants participation in the particular case. Having decided on this, his approach should carry that objectivity that is necessary to render his opinion of sound medical value to his legal associate in the trial of the case. Prior to the actual trial, he should spend the time necessary in going over the medical aspects of the evidence with the lawyer, reviewing for him the strong and weak points in the case and laying down an actual plan

of trial procedure by which the fullest value of the expert's experience is obtained through the avenues of direct and redirect examination on the witness stand. This type of preparation should be followed uniformly, whether the case be of serious criminal nature involving the life or liberty of the defendant or whether it be of the nature of a civil or compensation case. In so doing he will be rendering proper service through his professional training and experience to the cause of sound medical jurisprudence, something that is sorely needed in this country, and that, I might add, is the inescapable social responsibility of every physician at this time.

Meadowbrook Hospital.

DIAGNOSTIC USE OF RADIOISOTOPES IN A GENERAL HOSPITAL

R. W. Emerick, M.D., L. E. Holly, M.D., A. H. Joistad Jr., M.D.

and

K. E. Corrigan, Ph.D., Muskegon, Mich.

Four and one-half years ago a radioactive isotope program was started at Hackley Hospital in Muskegon, Mich. This city is situated about 200 miles from any large diagnostic and clinical center, and it was thought that the demand for radioisotope studies was sufficient to justify establishing such a program in a small general hospital. Our experiences in establishing and maintaining this program will be presented.

In setting up such a program certain factors must be present to assure continued and successful operation. First, and most important, there must be a demand for the services offered. There must also be adequately trained personnel available to administer and operate the department. Physical equipment and space must be available, and protection standards must be maintained. We felt that the demand for radioactive isotope facilities was present. This was due, in part, to the presence in the community of physicians trained at larger centers where such services had been available. Other physicians had become interested as a result of papers appearing in various scientific journals. We were able to form a radioactive isotope committee and meet the requirements established by the United States Atomic Energy Commission. One of us (K. E. C.) became available as radiation physicist on a part-time basis.

An elaborate outlay of equipment is not necessary. One good Geiger-Müller counter giving reproducible and reliable counts is necessary. We have found that, in a small community without the services of a full-time physicist, a standby Geiger-Müller counter is of great help in case of mechanical failure. We use a shielded counter tube with an aperture of 2 cm. that, with a detachable cone, can be reduced to 1 cm. (figure). This will localize small active sources within 0.5 cm., which is entirely satisfactory from a clinical standpoint. In addition to the Geiger-Müller counter it is imperative to have a radiation survey meter to monitor radiation from a protection standpoint.

A high-level radiation laboratory is space consuming, and it is a source of considerable expense in obtaining proper protection and the necessary special instruments. We have solved this problem by having the isotope section of the radiology department at Harper Hospital in Detroit standardize and dilute the concentrated solutions as received from Oak Ridge. We handle the diluted solutions in a low-level radiation laboratory where adequate protection is attained in minimal space with very little special equipment. Such dilute solutions may now be obtained by qualified departments from various commercial sources. The particular radioactive isotopes used for diagnostic purposes are determined by the needs of the local medical group. In our community we have had no experience with radioactive sodium, diiodofluorescein, or iodinated human serum albumin. Our surgeons still prefer the microscope to radioactive phosphorus (P^{32}) in establishing the character of tumors. With only six exceptions, when P^{32} was used for tumor studies, our diagnostic studies have been made with radioactive iodine (I^{131}). This may be explained by the fact that in our community we have no neurosurgeon, thoracic surgeon, or vascular clinic. The vast majority of our studies have been done at the request of general practitioners or internists who view with suspicion the results obtained with the usual apparatus for determining basal metabolic rates and wish an accurate evaluation of thyroid function. We are gradually getting more referrals from surgeons as they realize the advantage of knowing before surgery the location of the pathological areas within the gland.

Patients for diagnostic radioactive iodine studies are hospitalized for approximately 48 hours. This is partially for our own convenience and partly to facilitate excretion studies. The usual tracer dose is 50 μ c of I^{131} , or, in children, proportionate amounts according to body weight. This is given orally to the patient, who has an empty

stomach, about 8:00 a. m. the first morning. The first of the survey counts is started about two hours later. Two additional examinations are made on the first day and at least two examinations on the second day. In making these counts, definite locations over the thyroid region are studied each time. In addition, a general survey of the gland area and supraclavicular regions is done to locate any hyperactive or aberrant localizations. Counts are also made over the episternal notch, manubrium, and body of the sternum to locate possible retro-manubrial or retrosternal extensions of the gland. In this manner we can determine the rate and degree of uptake of iodine by the thyroid gland as a whole, and we can also detect localized variation within the gland. Counts of the liver, stomach, and thigh are also made at each examination. This checks on rapidity of absorption from the gastrointestinal tract, retention of the radioactive iodine in the soft tissues, and remobilization of iodine in the liver.

Small aperture attachment for the counting tube, which is readily attached and reduces the aperture to 1 cm. diameter.

All urine is collected, and the time and quantity of output is recorded. A sample of each urine specimen is obtained and later assayed for radioactivity. In this manner we obtain an excretion curve that can be correlated with the uptake curve of the thyroid gland. We feel that 90% of the administered iodine must be accounted for, and the other 10% can be accounted for by fecal loss, loss in perspiration, and extra-thyroid retention.

TRACER STUDIES

Since beginning our radioactive isotope program we have made 412 tracer studies. Of these, six were done with P^{32} for tumor localizations. All other tracer studies on thyroid function have been done with radioactive

iodine. There has been a marked range in age grouping among our patients, the youngest being five months and the oldest 85 years. It is beyond the scope of this paper to analyze fully the results of all of the cases that have been studied. This will be done in further publications. The breakdown of the diagnosis made is, however, of considerable and acute interest. Twenty-eight studies were done on children or infants. Ten of these were done on seven children who had osteochondrosis of the capitular epiphyses of the femur (Legg-Perthes disease). The studies revealed either thyroid hypofunction or the presence of toxic adenomas. This is in agreement with previous reports by Reynolds and others¹ and by Corrigan and Corrigan.² Radioactive iodine has also enabled us to differentiate hypothyroidism and mongolism in infants.

Of the adult group, thyroid function was normal in 11 patients. Generalized hyperfunction of the thyroid was present in 19 patients, and clinical findings of exophthalmic goiter (Graves' disease) were present in 6 of these. Thyroid function had generally decreased in 16 patients. In 79 patients one or more toxic adenomas were found in the thyroid glands. Submanubrial or substernal extension of the thyroid gland with varying degrees of intrinsic activity was discovered in 80 persons. In these patients, eight glands were postoperative residual or recurrent. In 21 patients mixed gland conditions were found. Colloid goiters were studied in three patients, and in four patients there was no appreciable thyroid function. Degeneration of the thyroid gland was considered to be possible in 18 studies. Metastases from thyroid carcinoma were found in two patients. In five patients thyroid carcinoma was present. Marked circulatory embarrassment was present in three patients, ruling out the possibility of evaluating thyroid function. In 12 patients occult edema was discovered. A definite chemical block was present in 29 instances and to a lesser degree in 21 other patients. Three studies were completely unsatisfactory.

COMMENT

The above results given in rapid-fire order, and without a chart to further clarify them, are confusing. The important point is not the number of patients for whom any certain results were obtained, but that, with the exception of three small groups, the diagnoses could not have been made with any of the single measurement or single time of measurement techniques. We wish to reiterate the statements made before the Section on Radiology by Reynolds and others¹ in 1952: "The criteria of adequate tracer study are: (1) anatomic location of the tissue that metabolizes the isotope, (2) rate of uptake and total uptake of tissue, (3) discontinuities and non-uniformities in tissue masses found, whether in normal thyroid region or elsewhere, (4) rate of decrease of any localization that shows unusual decrease from its maximum concentration, (5) the total urinary excretion, and (6) the shape of the excretion curve." These are not easy criteria to meet, and fulfillment of them requires well-trained and interested personnel. It also requires considerable expenditure of time and energy. Methods may be developed in the future that will ease their accomplishment, but the basic criteria will remain.

1. Reynolds, L.; Corrigan, K. E., and Hayden, H. S.: Detection of Concealed Thyroid Disease by Tracer Technique, *J. A. M. A.* 151:368-371 (Jan. 31) 1953

2. Corrigan, K. E., and Corrigan, H. S. H.: Tracer Studies in Children with Legg-Perthes' Disease, exhibit at annual meeting, the Radiological Society of North America (Dec.) 1951.

The number of chemical blocks of the thyroid gland that have been encountered is high despite careful screening of patients. As referring physicians become more acquainted with the problem, the number of blocks is decreasing, and the problem is becoming less vexing. It is certain, however, that even under optimum conditions a certain amount of unmentioned self-medication will be present. One drawback of the tracer procedure is the expense of hospitalization for two days. If and when physical facilities allow, a selected group of patients may be examined on an outpatient basis and be allowed to collect their own urine specimens. Considering some of the difficulty that we have had with nurses and ward helpers, patients may do as well on this basis as by being hospitalized.

SUMMARY AND CONCLUSIONS

In our experience in a small general hospital, the bulk of diagnostic radioactive tracer studies has consisted of radioactive iodine tracer studies of the thyroid gland. Our method of procedure, with a general discussion of results and shortcomings, is presented. We believe that, as other diagnostic procedures are developed in larger centers, they will be reflected in our procedures. In our experience, establishment of a radioactive isotope department in a small general hospital is a feasible and practical procedure. In this way the advantages of these tracer studies may be extended more generally to aid the practice of medicine.

878 N. 2nd St. (Dr. Emerick).

THERAPEUTIC VALUE OF RADIOISOTOPES IN A GENERAL HOSPITAL

Carleton B. Peirce, M.D., F.A.C.P., F.R.C.P., Montreal, Canada

Consideration of the value of radioactive isotopes as therapeutic agents in a general hospital naturally requires an assessment of their characteristics and usefulness, either as substitutes for less available or less safe instruments presently at hand or as a means to appreciably advance the treatment of disease. The value of any physical agent or drug depends in some degree on its qualities and properties but more importantly on the knowledge, skill, and intelligence of those who apply it. Such is particularly true of the radioactive isotopes, for which there is no antidote and in whose administration there is no reversible reaction. In fact, the isotopes are more dangerous for both the giver and the recipient than those agents that were previously used, and certainly will be more hazardous than helpful if those who attempt to employ them are not fully prepared both physically and intellectually and blessed with better than average judgment.

The early investigation of physiological applications of the radioactive isotopes produced in a cyclotron fortunately was limited by the available quantity. With the advent of the nuclear reactor and its potentialities for greater productivity and variety of the unstable isotopes, the general public and also the medical profession have tended to clamor for another group of "wonder drugs." Little heed has been taken of the fact that the isotopes are not so plentiful nor so innocuous as broomsticks nor graced with altogether bewitching qualities for the discovery and cure of disease. The informed members of the profession are fully aware that the unstable isotopes can be as malevolent and as productive of toil and trouble as Macbeth's witches and their brew.

Before any consideration is given to the use of these agents, there must be acknowledgment by the administrative boards of the hospitals, in spite of their desire that the institution be in the forefront in their community, and by the attending staff, with the desire to do all possible for the benefit of the patients, of the grave responsibility that they propose to undertake in the use of radioactive isotopes. This is a field that will be in the category of research for some time.

Certain minimum requirements as to personnel and physical plant have been laid down by government as prerequisite to permission to procure radioactive isotopes. It is extremely important that the philosophy and urge of "free enterprise" do not bring harm to patients by the observance of these requirements only in the letter of the law rather than in the full spirit. Hence, no hospital should consider the use of the unstable isotopes unless it and its medical staff are fully prepared to sacrifice time and funds, to submerge personal ambition and desire, to work closely as a team in the best interests of the patients, and to realize and accept the responsibility of research in this as yet inadequately charted field.

At present, the types of disease and number of patients peculiarly suitable for treatment with the available radioactive isotopes is limited. Without adequate staff and adequate number of cases for comparative study, no general hospital should try to explore the diagnostic or therapeutic applications of radioactive isotopes.

The second consideration in assessment of the potential value of radioactive isotopes is the purpose for which they may be used, namely (1) as substitutes for agents previously available, either as equivalent in usefulness but (a) more readily available, (b) of greater versatility, (c) of greater power, or (d) with less potential side-effects or hazard; or (2) with the capacity to do a new job, such as by means of selective physiological affinity for a specific organ or tissue. It is evident at once that criteria of (a) physical characteristics and (b) biochemical or pharmacological suitability must be established; and in general each specific isotope will have to be scrutinized under both headings. This is not so necessarily rigid in the matter of substitution for external irradiation as for intracavitary, interstitial, or parenteral administration.

GENERAL CONSIDERATION OF AVAILABLE ISOTOPES

Of the known and probably existing 1,052 isotopes and isomeric pairs, 282 are stable, and 118 have a half life measured in seconds, 199 in minutes, and 96 less

From McGill University and the Royal Victoria Hospital.
Read in the Symposium on the Use of Radioisotopes in a General Hospital before the Section on Radiology at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

than 12 hours. Subtracting these and the 49 naturally radioactive elements and their isotopes, there remain some 209 unstable isotopes with half lives of from more than 12 hours to 60 days and 99 whose half lives extend from 60 days to more than 1,000 years. Those with a half life less than 14 hours are relatively impractical and afford some extra hazard; those of greater than 30 to 40 days are not safe for parenteral use. The remaining portion of these active isotopes (about 70) must be studied extensively as to their physical and pharmacological qualities before adequate assessment can be made of their therapeutic value. Only a few, so far, have been shown to be producible in practical quantities with present facilities, to possess suitable and useful physical characteristics, and to be pharmacologically safe and physiologically useful.

The physical usefulness of the radioactive isotopes depends chiefly on their emission of either beta or gamma radiation, the energy of that radiation, and their half life. So far, for external therapy, phosphorus 32 and strontium 90 have had a fair clinical trial among the beta emitters and cobalt 60 among the gamma sources. All three fall into the category of substitutes for presently available radium sources.

For intracavitary administration, sodium 24, phosphorus 32, cobalt 60, bromine 82, and gold 198 in various forms and with various techniques have been found useful. These, save phosphorus and gold, are present substitutions for previously available but less facile radium. Gold 198 and phosphorus 32 in colloidal form are examples of physiologically useful isotopes in the management of serous membrane malignant effusions. About 27 active isotopes possibly are usable internally. The specific avidity of various organs or tissues for a high majority of these is not known. Consideration of the parenteral administration of radioactive substances must include study of not only the full gamut of the alpha, beta, or gamma emission and the half life of each substance but also very specifically the pharmacological safety and biological activity or physiological progress through the tissues. So far only iodine 131 and phosphorus 32 have been proved acceptable.

These various facets of the use of radioactive isotopes emphasize the absolute necessity for a full complement of medical staff, including persons especially experienced in clinical physiology, pharmacology, metabolism, hematology, endocrinology, radiation therapy, and radiobiology, together with radiation physicists and a corps of trained technicians, as well as the required physical plant and instruments to be available in every general hospital that presumes to treat disease intelligently with these physical agents; for this entire field still remains in the realm of research and must be subjected continually to critical review.

SPECIAL CONSIDERATION OF VARIOUS ISOTOPES

With this relatively brief discussion of the general problems associated with the therapeutic use of radioactive isotopes, we may pass on to an even more brief commentary on the few isotopes that have been studied so far.

External Irradiation.—The choice of a radioactive isotope for external therapeutic application must be predicated on availability, its relative safety, facility of manipulation, and the superiority of its radiation as to either (a) virtual total absorption in the superficial millimeters of the tissue, thereby effecting a more satisfactory biological reaction than available with low or medium voltage x-radiation or radium; or (b) a high energy level of sufficiently short wavelength and relative monochromatic character to effect superior depth-doses compared to high-voltage x-radiation or large quantities of radium.

Phosphorus 32, with a half life of 14.3 days, emitting only beta radiation (1.7 mev) with a range of 7 mm. in tissue, appears to be useful in treatment of superficial carcinoma of the skin, some keloids, and localized keratoses. The blotting-paper technique of Low-Beer has been improved on by Sinclair, Blondal, and Smithers at Royal Cancer Hospital by means of the incorporation of 20% red phosphorus (by weight) in polyethylene that can be pressed into thin, flexible, glossy-surfaced sheets before activation in the nuclear reactor.

Strontium 90 (half life 25 years, beta radiation of 0.65 mev, no gamma radiation) in a surface applicator has been shown by Friedell and Thomas to be of significant value in the treatment of the benign vascular lesions of the conjunctiva and cornea. This is an addition, or rather an advance over the older radium D/E applicator.

Cobalt 60 (half life 5.3 years, with an almost monochromatic gamma radiation [1.16-1.32, average 1.25 mev]) affords a relatively ideal agent in the second group for the treatment of deep-seated malignant lesions. A cobalt 60 source of 1,500 curies equivalent can be provided in the nuclear reactors with high flux. Its high activity will afford an energy output of approximately 40 r per minute at 80 cm. source-skin distance. Its use should be restricted, however, to only those therapeutic centers that have at least 300 new cases of major malignant neoplasms per year (to afford sufficient numbers of patients and for selection of cases), that have full staffs, including experienced radiation therapists who personally direct the treatment, observe their patients daily, and are aware of the hazard of high exit doses and the lack of the usual skin reactions common to more conventional x-radiation. The collimation of the beam with reduction of penumbra to a minimum presents a real problem in engineering physics, which we believe has been solved most satisfactorily by Prof. H. E. Johns.

Intracavitary Irradiation.—The selection of isotopes for irradiation of malignant disease within a cavity will depend on whether the lesion is sufficiently thin and widely distributed to utilize beta radiation or its depth and location necessitate a gamma source. Hollow cavity or viscus: A solid source, to be molded or compounded to fit a known cavity, can be afforded by shaping cobalt into a special form or by using beads or pellets. However, inasmuch as metallic cobalt is absorbable by body fluids, a source of whichever shape must be plated with gold or encased in platinum and then activated in the "pile." Certain technical difficulties in proper introduction or fixation of such sources and problems of hazard to per-

sonnel in handling them in this manner must be appreciated. Cobalt 60 can be used thus in carcinoma of the cervix and carcinoma of the maxillary antrum. It also may be employed in cylinder form as a point source suspended in the urinary bladder.

Walton and Sinclair have reported on the rather satisfactory use of sodium 24 (half life 14.8 hours, beta radiation of 1.4 mev and gamma radiation of 2.76, 1.38) in sodium chloride solution, or bromine 82 (half life 34 hours, beta radiation of 0.47 mev and gamma radiation of 1.35, 0.79, 0.55) in calcium bromide solution in a 150 ml. balloon attached to a catheter in selected cases of carcinoma of the bladder in which the lesion does not extend deeper than the submucosa. In their experience, three fractionated doses of $2,000 \gamma r + 500 \beta r$ each at weekly intervals was more satisfactory than a single dose of $3,000 \gamma r + 4,000 \beta r$ for sodium 24 or $4,000 \gamma r + 1,000 \beta r$ for bromine 82. In the female, this balloon may be introduced via the urethra; in the male, via a small incision in the perineum and the posterior urethra.

Serous Cavity (Pleura or Peritoneum): Modification and retardation of serous effusions in those patients with embarrassing pleural effusion or ascites due to disseminated metastatic neoplasm (chiefly from the breast or the ovary) have been accomplished with colloidal gold 198 or colloidal chromic phosphate. The short half life of Au^{198} (2.7 days, approximately 95% beta radiation, 0.96 mev maximum, gamma radiation 0.41) reduces its usefulness at appreciable distances from the source of supply; hence some investigators have recently used the colloidal chromic phosphate with its advantage of the longer half life of phosphorus.

Such colloidal suspensions must be physiologically harmless, must have a particle size large enough to prevent dissemination, must be sufficiently stable to prevent an uneven precipitation, must be available in high specific activity to avoid use of large volumes, must have a short half life to enable delivery of dose in a reasonably short time, and must emit predominantly beta radiation for local effect on the serous membrane but sufficient gamma component to permit external detection of the distribution. Neither gold 198 nor colloidal chromic phosphate can be expected to affect large masses of metastatic neoplasm. Reports on both indicate appreciable reduction of accumulation of effusion may be achieved.

Interstitial Irradiation.—So far cobalt 60 and tantalum 182 (half life 111 days, beta radiation 0.5 mev maximum, gamma radiation 1.13) and gold 198 have proved of value in interstitial therapy of malignant lesions. The absorbability of cobalt has been mentioned. This requires that any Co^{60} source must be sealed in some physiologically inert material. It is more brittle and more expensive than tantalum. Tantalum is physiologically inert. Its higher density, considerably higher specific activity with a gamma radiation of relatively the same wavelength further recommends the use of tantalum. In all interstitial use, local reaction due to beta radiation and alpha radiation of the source material must be reduced to a minimum. Cobalt 60 requires encasement to prevent absorption, and all three (Co^{60} , Au^{198} , and Ta^{182}) should be sheathed in order to reduce or remove the beta component emitted. The relative intensity of Co^{60} is of the order $13.5 r/hr./mc.$ compared with $6.1 r/hr./mc.$ for Ta^{182} .

Gold 198 grains can be used as a substitute for radon seeds; however, these should also be encased in platinum or plastic. In general, they do not appear advantageous compared to radon in gold seeds. Considerable study is being pursued by the University of Iowa group on the interstitial injection of colloidal gold 198 in prostatic malignant disease. Some encouraging evidence has already been accumulated, but this work is distinctly still in the research phase. The general hospital that admits less than 500 new patients with malignant disease in a year will have little use for intracavitary or interstitial means of treatment with radioactive isotopes.

Parenteral Administration.—Therapeutic use of radioactive isotopes by the parenteral route requires first that the active element and its compounds are not toxic and are physiologically useful to the tissue that one desires to affect. Secondly, the active element must not be one that the body may substitute for another (such as strontium 89 or yttrium 90 in replacement of calcium in bone), transfixing the element in tissues that are not to be irradiated; nor must the element have undesirable radiation quality or half life.

Selection for therapeutic value will depend on: (a) the degree of selective chemical affinity or use that a specific tissue or cell type has for the element and the metabolic activity of that tissue or cell; (b) the degree to which the "uptake" (by either absorption or utilization) will be effected without material deleterious physical or chemical effect by the element or its carrier on other cells, tissues, or the body as a whole; and (c) the extent to which its radiation will benefit the local cell or tissue, an intimately neighboring tissue complex, the whole organ or entire body, with less deleterious effect on the tissue or whole organism than some other therapeutic agent.

Radioactive Iodine: It is readily apparent that radioactive iodine meets virtually all the above-mentioned criteria in regard to thyroid disease. The selective chemical affinity for and use of iodine by the thyroid gland, with little need for iodine in other organs or tissues save as protein-bound in thyroid hormone, is peculiarly favorable. The association of disturbed thyroid metabolism with other metabolic and certain cardiovascular dysfunction increases the value of this agent. Its half life of 8 days, with beta radiation of 0.595 mev penetrating about 2.2 mm. and adequate gamma component to permit external detection in both mass and detail, as well as dominant excretion via the urinary tract, make this isotope an almost ideal example.

The two previously established means for treatment of thyroid dysfunction are not entirely satisfactory. Surgical subtotal resection in the best of hands affords control in but little over 60% of those operated on, has today a small but definite mortality risk, includes some hazard to the recurrent laryngeal nerve and parathyroid glands, requires hospitalization, and is not always practicable.

The antithyroid drugs have afforded better means of preparation for surgery, to a certain degree allow election of time for surgical intervention, and in some cases have "relieved the patient of his symptoms while he cures himself" (Blomfield). But the long-term results tend to be disappointing, not over 50% stabilize after one course, the patient tends to revert to his thyrotoxic state when

the drug is withdrawn, and the toxic side-effects of propylthiouracil and methylthiouracil (agranulocytosis, drug sensitization) are not favorable.

The gradual depression of thyroid hyperfunction afforded in the specific cellular depletion of the gland by I^{131} without damage to other tissues is a strong recommendation for its use, especially in selected cases. Hospitalization is not required; there is no surgical hazard nor toxic side-effect. Certain observers consider that exophthalmos is reduced to a greater degree than with surgical ablation. Neither pressure symptoms nor cardiac complications are significant as contraindications. The gland reduces in size, and there is certainty of correction of dysfunction in time, with supplemental dose if required. Large series or groups of series for statistical analysis are not yet accumulated. Some observers believe that 85% of patients can be brought to a euthyroid state in about 3.5 months with a single dose.

At our present state of knowledge in the matter, the indications for I^{131} therapy are: (a) diffuse toxic goiter in patients over 47 years of age, (b) diffuse toxic goiter in younger patients when antithyroid drugs fail and surgery is refused, (c) hyperthyroidism complicated by, or associated with, cardiovascular disease, and (d) recurrence after surgical intervention. The major contraindications appear to be: (a) acute hyperthyroidism in younger patients, (b) pregnancy, and (c) nodular goiter. In each case, however, serious consideration must be given to the possible advisability of either surgery or a test of the antithyroid drugs in preference to I^{131} . In patients under consideration for I^{131} therapy, careful tracer studies should precede decision. These must include basic and subsequent periodic mass counts, together with careful scanning of the thyroid area for irregular uptake, and urinary excretion counts over at least 24 hours, preferably longer. Assessment of the resultant curves is not valid unless compared with similar studies of presumably normal persons residing in the same geographic area. Supplementary or comparative observations on the basal metabolic rate, blood cholesterol, and serum protein-bound iodine are important. We find that hospitalization, or at least day hospitalization, of the patient is necessary, in order to obtain adequate periodic counts and to collect the urine for excretion determination.

The dose considered therapeutic for nonmalignant thyroid disease varies from observer to observer, and in any one group there will be an appreciable variation in effectiveness dependent on the metabolic activity of the patient and his thyroid. We consider at present that it is better to administer a standard dose and repeat it in three to four months if required. The optimum average dose is probably in the range of 8,000 to 10,000 rep. Some have been brought to a euthyroid state with 4,800 rep.

A latent period of two to three months is to be expected before radiation effects are clinically manifest. Antithyroid drugs may be required during this period. Careful reassessment is necessary before any supplemental dose is administered. If the response to the initial dose has been rapid, further delay before additional treatment is advisable. The clinical reaction must be observed closely, especially as to remission of symptoms, change in size

of the gland, and subsidence of tachycardia or other cardiovascular signs; together with any alteration of the peripheral circulation.

It should be emphasized that similar results can be produced with properly managed conventional x-radiation of the thyroid. Therefore, unless a general hospital determines that it has real need for and must inaugurate an isotope program with its attendant requirements of staff and physical plant, if that institution has adequate therapeutic x-ray apparatus properly operated by a well-qualified and experienced therapist, there is not sufficient additional value in radioactive iodine therapy to warrant the required investment and additions to staff for that alone.

Since Hamilton's first observation and Seidlin's initial report on treatment of malignant thyroid neoplasm with I^{131} there has been little advance in methods or means to cause the predominantly non-iodine-metabolizing thyroid malignant lesions to utilize radioactive iodine. The early small, palpable, nodular tumor confined to the thyroid gland and without metastases is best managed by surgical removal of the lobe or subtotal thyroidectomy, with or without dissection of all regional nodes. For the large, rapidly growing mass, with or without pressure complications, radioiodine therapy is too slow and x-radiation preferable.

In the realm of distant metastatic deposits, I^{131} seems to have some appreciable value, especially if the thyroid gland has been removed almost entirely. Total body tolerance of the relatively high dosage required is an important factor in conjunction with the avidity of the gland proper or its metastases for the active iodine. The antithyroid drugs and thyrotropic hormone may assist, but there is some hazard in the precipitation of a myxedematous state by the administration of large doses of thiouracil for some weeks and then sudden withdrawal in preparation for a therapeutic dose of I^{131} . The total number of cases of carcinoma of the thyroid in even large centers for diagnosis and treatment of malignant disease of all kinds is so small that no general hospital is warranted in providing for this type of treatment especially.

Phosphorus 32: Hope has been entertained that phosphorus, required in the normal metabolism of bone and a common constituent of the hemopoietic tissues and cells would prove to be of specific value in the blood dyscrasias and malignant diseases. Considerable numbers of observations have been made as to its effect in acute and chronic leukemia, polycythemia, the malignant lymphogranulomas and lymphosarcomas, and multiple myeloma.

So far there is some evidence that phosphorus 32 offers significant advantage over the more ancient methods and means. However, the general hospital, well-staffed and equipped for proper roentgen therapy and with members skilled in the use of chemotherapeutic agents in these malignant diseases, as in the case of radioiodine, should not embark on an isotope program for this alone and should include such treatment in a general isotope research plan only if its clientele includes annually an appreciable number of such cases.

SUMMARY AND CONCLUSIONS

The radioactive isotopes afford, in but a few instances so far, means whereby nonmalignant and malignant disease may be controlled more easily or less expensively than with the older or more accessible methods. The use of virtually all of these isotopes is still in the field of clinical research.

Cobalt 60 is at present useful as a substitute for 3 million volt x-radiation in deep-seated malignant disease. Its use should be restricted to centers having large numbers of new cases per year, in order to afford adequate selection and comparison of the clinical material for research purposes. Strontium 90 in a surface applicator can be used for vascular lesions of the conjunctiva and cornea and is an improvement over the radium D/E applicator. Colloidal gold 198 and possibly phosphorus 32 in a colloidal chromic phosphate preparation can be used for the amelioration of serous or sero-hemorrhagic effusions in the pleural or the peritoneal space associated with disseminated malignant disease.

Sodium 24 or bromine 82 in solution, encased in a plastic balloon, are useful for the treatment of widespread

superficial carcinoma of the urinary bladder. Cobalt 60, tantalum 182, and gold 198 offer considerable promise for interstitial irradiation as substitutes for and possibly improvements upon radium and radon. Iodine 131 has proved to be so far the nearest approach to the ideal radioactive isotope for parenteral and selective therapy of thyroid disease. Phosphorus 32 has certain possibilities in the dyscrasias and neoplasms of the hemopoietic tissues.

In general the entire study of radioactive isotopes as therapeutic agents is still in the realm of research and should be so considered. No general hospital (a) that discovers and treats fewer than 500 new cases of malignant disease or 100 of thyroid disease per year, (b) whose staff is not fully diversified and especially skilled in clinical physiology and radiation therapy, with an experienced radiation physicist or biophysicist, (c) whose staff will not subrogate all personal interest to close teamwork in such an investigative program, and (d) whose administration is unwilling or unable to afford the physical facilities required should consider therapeutic application of the radioactive isotopes at this time.

687 Pine Ave., W. (2).

THE RADIOISOTOPE PROGRAM IN THE GENERAL HOSPITAL

Edith H. Quimby, Ph.D., New York

The time is rapidly approaching when a radioisotope program in the general hospital will be taken as much for granted as any other laboratory service. Its scope will depend on the size of the hospital and the interests of the staff, but we can safely say that it will include thyroid function studies, blood volume determinations, radioactive phosphorus (P^{32}) therapy of leukemia and polycythemia, radioactive gold (Au^{198}) therapy for ascites incident to generalized abdominal or pleural carcinomatosis, and radioactive iodine (I^{131}) therapy for exophthalmic goiter. In addition, the radioisotope program may include localization of brain tumors and liver metastases, determination of extracellular fluid volume, isotope clearance measurements for various tissues, studies of peripheral vascular disease, and various types of therapy. Foreseeing this and also wishing to be among those to derive benefit from any new agency, hospital medical boards and administrators are studying procedures and requirements for inaugurating such a program. This includes, on the one hand, providing adequate space and equipment and, on the other, solving problems of personnel, training, procurement, and general techniques. The former considerations have been covered in the preceding discussion. I propose to discuss generally certain points regarding the others.

There has been, in some quarters, the feeling that the Atomic Energy Commission is unduly restrictive in limiting use of isotopes to trained personnel, under stipulated conditions. Let it be said at the outset that the commission is anxious to have as wide employment as possible, compatible with the safety of all concerned, of the non-military products of atomic energy. It is because of the

very real danger of injudicious use of these materials that the restrictions have been set up. Everyone is aware of the tragedies that followed early incautious use of x-rays and radium; it is essential to avoid a repetition of this. The primary concern of the Subcommittee on Human Applications is the safety of patients, doctors, technical staff, and possibly "innocent bystanders." Beyond this they may express an opinion as to the feasibility of a procedure, but they do not attempt to pass on its value. Feeling that responsibility for an isotope program should be vested in a group rather than in an individual, the advisory committee recommends that every institution wishing to use radioisotopes form an "isotope committee" to supervise and control use of these materials. Membership of this committee should include a hematologist, an internist, a person experienced in assay of radioactive materials and in protection of personnel against ionizing radiations, and, when possible, a therapeutic radiologist and a qualified physicist. The latter two are essential when therapy is to be done, although they may serve on a consulting basis and not be staff members.

In commencing a radioisotope program, the person who is to take the responsibility for patients must have some firsthand knowledge and experience in isotope uses. After he has acquired some experience in the uses of a few isotopes, he may make use of others without taking additional training, provided no new or great radiation hazards are concerned. In applying therapeutic pro-

cedures that have been developed elsewhere, a brief period of observation is recommended, even for experienced users of isotopes, since this may aid in avoiding pitfalls. Minimum criteria for the physician who will use or directly supervise the use of radioactive materials have been set forth by the Isotopes Division. He must be an accredited physician in good standing with his local medical society and must either have had previous clinical experience with radiation or radioactive materials or be directly collaborating with a person possessing such training and experience. Minimum experience for use of I^{131} , P^{32} , and Au^{198} includes three months' active cooperation in a group using these isotopes and a month of actually handling the isotopes and participating in the management of cases. Unfortunately, there is a scarcity of facilities for such training, especially in smaller towns. However, various institutions are beginning to offer short courses combined with visiting programs; it is hoped that before long this "bottleneck" will be removed.

The function of the radioisotope committee is to review applications for use of isotopes within the institution, primarily from the point of view of radiological safety, but they may also serve in any advisory capacity they feel is indicated. They should be an active group, keeping in touch with all the developments of the isotope program and not leaving responsibility to the chairman. They not only should approve a program at its inception but should review it regularly by means of progress reports. They must be in close touch with the radiation safety officer for the institution, who is usually a member of the committee.

The radiation safety officer will usually be either the physicist or the chemist in charge of the isotope laboratory, or the radiologist, or he may be anyone with the necessary knowledge. He has responsibility for maintaining radiation safety throughout the institution and should have authority to enforce his recommendations. He will make sure that all handling procedures are adequate for safety and will instruct personnel on cleaning up after any spill and on disposal of radioactive waste at any level. He will provide instructions for residents, nurses, orderlies, and other attendants not only to make sure that no dangerous habits are formed but also to make sure that no ridiculous extremes of safety requirements are set up. Such an educational program is frequently essential when the use of isotopes is started in an institution. Personnel who have never worried at all about patients who have fairly large quantities of radium in their bodies, such as women patients with cancer of the reproductive organs, suddenly become much concerned about patients with tracer or small therapeutic doses of isotopes. Assurance should be given that such patients present no hazard and that the only problems come with those receiving therapeutic doses in excess of about 30 mc. of I^{131} or Au^{198} . As for disposal of excreta from patients undergoing isotope tests or treatment, no special plumbing facilities are necessary. As a matter of fact, it is seldom that special instructions need be issued about this, unless urine or feces are to be saved for laboratory study.

In addition to the isotope committee and the radiation safety officer, the isotope laboratory must maintain at least one technician who will do the actual work of standardizing and dispensing the radioactive material and

doing the routine measurements on patients and specimens. Unfortunately, at present there are few places that train such technicians, which means that someone in the organization must be prepared to undertake this responsibility. If there is a radiation physicist, he will be qualified; usually the radiation safety officer will also be qualified. If this training is to be undertaken by a clinician, the isotope committee should make sure that he is conversant with fundamentals of Geiger counting, limitations of the instruments, and elementary statistics of counting (to give proper significance to background and other counts), and that he appreciates the value of plateau checks and frequent calibration and the significance of the geometric relations of counter and sample or patient. A technician can learn to use a counter in five minutes; it may take her as many months to learn how to avoid all the pitfalls between receiving the material from Oak Ridge and turning in a correct report to her supervisor. The dispensing of calibrated solutions by chemical houses or by consultants may minimize the chance for error in calibrating Oak Ridge material. On the other hand, it may give a false sense of security. The need for accurate pipeting and accurate application of decay curves is just as great and so is the need for all precautions regarding background, patient, and sample counting. College graduates with training in any of the laboratory sciences have made satisfactory technicians. It is felt that this type of education is highly desirable. A person with less schooling could certainly learn the procedures but would seldom be able to develop an intelligent understanding of them.

With the isotope laboratory ready to function, those who are to use the materials obtain from the Atomic Energy Commission copies of form 313 for each isotope and file their applications. The first application submitted should contain a list of the members of the isotope committee, with their qualifications, and an inventory of equipment available for measurement and survey purposes. This information never needs to be repeated in subsequent applications unless radical changes have taken place. On approval by the Subcommittee on Human Applications, isotopes may be obtained and work started. Some institutional authorities may be unwilling to commit space and invest funds for an isotope laboratory and equipment and then face the chance of having their application turned down. It may be said at once that, when an institution has complied with the requirements, it is extremely unlikely that authorization will be withheld. However, an acceptable alternative after establishing the local isotope committee is the presentation to the Isotopes Division of the equipment and space that will be acquired if the application is approved. Approval will then be issued contingent on completing the layout. The Isotopes Division maintains a consulting service that may be valuable in setting up an isotope laboratory in a hospital. Through correspondence they will answer questions on such subjects as methods, equipment, protection, and standards. They will also send a field consultant to give on-the-spot advice. Various professional consultants also offer such service.

As to the integration of the isotope laboratory into the hospital organization, few specific recommendations can be made. As tests become routine, they may be administered in the same manner as other clinical tests

such as those performed in the clinical laboratory. The result of the test may be reported without interpretation, leaving this to the physician who asked for it, or an interpretation may be furnished by the director of the isotope laboratory or his assistant. The first method can be illustrated by a report that simply gives the percentage uptake of radioactive iodine at 24 hours, without interpretation; this is the same procedure as used in giving the result of a basal metabolic rate measurement. On the other hand, a report of the percentage uptake might be accompanied by a statement as to its probable clinical significance. The former method could be used only in an institution where staff members were well aware of the significance of reported results. Therapeutic programs should be incorporated into the regular radiation therapy division; they are simply another form of radiation treatment. For special problems the radiologist will want to work in collaboration with other specialists, just as he does in the use of radium or radon interstitially.

While isotopes are comparative newcomers to the field of medicine, they have already been found valuable in many ways. There is no doubt that they will be applied more widely and that more and more general hospitals will establish units for their use. It is probable that units will generally be started on a relatively small scale to do the procedures most widely accepted, but provision should always be made for expansion of services and personnel, for this is inevitable in a progressive institution.

SPECIAL ARTICLE

MEDICAL ORGANIZATION IN NATIONAL CATASTROPHE

Melvin A. Casberg, M.D., Washington, D. C.

This report is concerned primarily with the standardization of surgical treatment of mass casualties in times of national catastrophe and certain organizational measures that are essential in effecting large-scale medical treatment. The responsibilities of our profession during times of disaster are grave, and the problems of organizing and directing the medical effort during such times are complex. To give some insight into the magnitude of this potential challenge to physicians, some of the surgical problems are reviewed.

In speaking of mass casualties, one enters a field that is foreign to the experience of American medicine, for our nation has never been confronted with the medical problems incident to the civilian catastrophe of modern total war. Nothing in our history has prepared us for the destructiveness of modern weapons, and even American civilian physicians who served in World War II had but little contact with the treatment of mass civilian casualties. Those who were experienced in these lines will find

that advances in both weapons and treatment have caused changes in medical thinking during the past decade.

It is difficult to grasp the magnitude of this potential challenge to the medical profession unless one realizes the modern concept of warfare. Historically, wars were fought by conscriptive armies who bore the brunt of trauma and who only indirectly drew upon the energies of the civilian population that supported them. This concept has become totally obsolete, and modern warfare is a matter of total national output to prevent total national destruction; the efforts of the civilian members of our society are as essential to the survival of a nation as the efforts of the combat forces. This change in concept is due to the tremendous advances in technology of modern warfare as well as the intricacies of a modern society. For example, it may take one bomber with a crew of three men to annihilate a target and materially weaken the enemy's ability to carry on war; yet behind this one bomber there lie the efforts of hundreds and even thousands of persons who participated in the creation of this weapon, commencing with the raw products of its component parts and going on to the finished machine. Therefore, future warfare probably will not differentiate between the military and civilian population, because to destroy the source of this bomber is just as effective, if not more so, than to destroy the finished product. This makes the civilian population in future wars more vulnerable to attack and disaster than ever before in history, and we should never delude ourselves into believing that humanitarian considerations will save us from wilful destruction when the enemy's survival may depend on the annihilation of our ability to produce lethal weapons. Although we sincerely hope that such a grim state of affairs will never materialize, American medicine must be prepared to handle mass civilian casualties, because in the ability of medicine to restore its civilian element may rest the survival of our nation.

In looking toward methods of handling mass civilian casualties, it is only natural that one looks to the armed forces, for they more than any other branch of American medicine have had experience in such lines. In this respect, it is essential to emphasize that there is no fundamental dichotomy between civilian and military medicine. Medical lessons learned in the armed forces are fully applicable should the civilian rather than the soldier become a victim of modern warfare.

MOVING CASUALTIES

An example of knowledge gained by medicine in the armed forces that can be applied in times of need to civilian practice is that of moving casualties. Patient evacuation has been an extremely important factor in contributing to lower mortality and morbidity rates of soldiers wounded in action and in times of national catastrophe could equally serve the interests of civilian casualties if intelligently applied. The ubiquitous helicopter with its almost unlimited directional capacity for short flights as well as the transoceanic and transcontinental range of the larger planes have given the wounded two major life-saving advantages, those of time and space, or in other words, early medical care in an environment best suited to bringing about recovery. On superficial consideration this factor of evacuation may not appear applicable to

civilian catastrophe. Yet in the event of critical major disaster to our larger metropolitan areas with resultant devastation of buildings and utilities, it may become necessary to transport our civilian wounded to adjacent towns for medical care. This would require the establishment of a medical organization patterned after that of the armed forces in combat operations with effective triage and rapid evacuation of patients as well as mobility of professional personnel.

In the event of an atomic attack on our nation, the problem of enemy air strafing of ambulance planes probably would not complicate the evacuation of patients within our continent, so that the only limitations would be those of the availability of planes and their operational facilities. Certainly in the case of critical destruction of certain of our large metropolitan centers there would be a distinct advantage in the evacuation of patients to surrounding or more distant satellite unharmed communities where definitive or even emergency care could be administered under a more normal environment. Unless one actually has observed air evacuation in action, it is difficult to appreciate the comfort, speed, and numbers of patients thus transported. Commercial transport planes should have incorporated under their plush cabin fittings the necessary attachments to support stretchers should the necessity for such conversion arise. When this is done at the time of manufacture the cost is insignificant and the availability in the event of emergency almost immediate.

CONTROL OF PATIENT FLOW

The armed forces have learned the necessity for a regulating office responsible for the direction of "patient flow." Such an organization insures the smooth evacuation of the sick and wounded to facilities that, from the standpoint of space available and professional care, are capable of handling the casualty influx. This unit does not have clinical professional responsibilities as does the triage team but acts on submitted diagnostic information to maintain a constantly revised "patient flow chart." It goes without saying that an adequate communications system is essential to the success of such a project.

There is nothing that can upset supporting medical facilities as thoroughly as poor sorting or classification of the sick and injured. By the same token intelligent triage performed by professionally competent personnel can not only save lives but also contribute to the optimal use of health personnel and facilities. A certain degree of honest difference of opinion exists as to the placing of various categories of medical personnel in the theater of combat. Nevertheless there has developed during and since World War II a majority opinion that a high level of professional competence must be located in close support of the line of combat. In an atomic disaster in this country one would not be faced with the problem of exposing professional personnel to continued enemy action, as is usually the case in combat situations; thus, this problem would not impose serious restrictions in the placing of health personnel at the site of disaster. This does not imply that the health professions are any more or less averse to exposure to danger but rather that, as is the case in war, this nation cannot jeopardize a critical personnel element without just cause.

Intelligent clinical judgment in the evaluation of the injured at forward echelons near the site of an atomic explosion will lessen the load imposed on the evacuation system by eliminating those with minor injuries and by the same token prevent an overcrowding of hospital facilities to the rear. Good professional judgment will make it possible to hasten the evacuation of those needing immediate care and sidetrack those with less urgent medical needs. The correct functioning of the triage team is contingent on the competence of its professional members. It is possible for a skilled orthopedist or surgeon, without even handling a scalpel, to save many lives by the application of sound clinical judgment in the triage of patients. The triage team must be familiar with the capacity, location, and competence of various supporting medical elements in order to function effectively.

The armed forces have learned from experience the value of small mobile surgical teams, both general and special, as supporting units to the forward echelons. The mobility of these units makes it possible to fit them into the evacuation chain where the flow of casualties demands special attention. One of the more recent specialty organizations that has developed in the evolution of this program is that of the vascular surgical team, and by virtue of the critical nature of this particular problem such a team holds a high priority in the evacuation chain. Certainly those responsible for the civil defense medical organization of professional personnel would do well to plan for mobile surgical teams to operate when and where the necessity arose. Actually all medical units should be organized primarily on the basis of personnel composition rather than geographic assignment, inasmuch as the latter is determined to a considerable extent by the site of the atomic explosion. The armed forces medical units under combat conditions are designated numerically as professional composites and not geographically, thus attesting to their mobile nature and ability to fall readily into the pattern of patient flow.

STANDARDIZATION OF PROCEDURE

Standardization in the application of therapeutic principles is quite distasteful to most of the medical profession, for this procedure is usually tainted with the aroma of mental regimentation and the shackling of individual scientific resources. Furthermore, there frequently develops a certain degree of retardation in the flow of medical progress when therapy is limited to the narrow confines of standard orders of procedure. Nevertheless there are certain conditions under which mortality and morbidity rates may be improved by the application of standard therapeutic principles. These conditions or modifying factors usually are existent in the medical problems precipitated by total war or a catastrophe of similar magnitude.

Whereas in civilian medicine the patient usually remains under the care of a single physician, the complications of war or physical catastrophe necessitate a series of patient evacuations with a multiplicity of health personnel and a variety of professional competence responsible for the treatment of the wounded. Therapy initiated at a forward echelon of medical installations is continued along the chain of evacuation with a series of professional men and women each contributing to the eventual recovery.

ery of the patient. This situation precludes too great a latitude in individual choice lest initial therapy narrow the limits of ultimate definitive care to the patient's detriment. For example, though different methods of soft tissue wound therapy are advocated by competent medical authorities, all do not lend themselves equally well to the care of the soldier, sailor, or airman injured in line of duty. Though an individual medical officer may be desirous of using his particular therapeutic measure, he must learn to conform lest the initial local treatment set the course of future definitive care in a pattern foreign to the personnel and facilities available in the chain of evacuation.

WOUNDS OF THE EXTREMITIES

Experience during World War II¹ and the more recent Korean conflict has shown that 70% of combat wounds involved the extremities and with the introduction of the armored vest this percentage is rising to an even higher figure. In an atomic attack actual trauma aside from burns will be inflicted in great part by secondary missiles or flying debris due to blast effect and certainly the extremities will receive a high proportion of these injuries. While the 4% mortality rate from this category of combat wounds is comparatively low, we must not lose sight of the serious long range handicap resulting from ineffectual limbs and therefore must bring into play every available therapeutic procedure that can contribute to the early rehabilitation of the patient. Though not necessarily applicable to civil defense, it is of interest to note that since the use of armored protection of the thorax and abdomen the over-all mortality rates have been lowered; however, in respect to the multiple low velocity fragment wounds of the extremities the morbidity rates are actually increasing. This somewhat paradoxical situation has developed because previously patients who sustained multiple serious wounds of the limbs also sustained similar injuries of the body trunk and did not survive, whereas under present protective elements the combat soldier lives but often with seriously mangled extremities. In the light of the importance of this particular subject we might in the first place give consideration to certain more or less standard emergency therapeutic procedures directed toward rehabilitating those with injuries of the extremities. Frequently the initial care will either save a limb or militate against its survival as a functional unit.

Hemorrhage.—Hemorrhage from a wound of the extremity is usually controlled by pressure dressings. In general the tourniquet should be used infrequently. When, however, the application of a tourniquet is indicated to prevent life-endangering hemorrhage, only rarely should it be removed before the wounded man has been hospitalized where facilities and personnel are available for operative control of the hemorrhage and for adequate blood replacement. The time-honored custom still accepted by many that the tourniquet should be removed every 30 to 60 minutes in order to minimize chances of gangrene of the extremity is a fallacious concept, for only an injury to the major vessel is likely to require a tourniquet and the incidence of gangrene in these, particularly in the lower extremity, is high regardless of the emergency measure applied. Furthermore, removal of the

tourniquet may facilitate another hemorrhage that in an already exsanguinated patient may very well prove lethal.

The tourniquet has enjoyed a rather fluctuating popularity, sometimes riding the very crest of acclaim and at other times settling low in the trough of discredit. To the medical novice in traumatic surgery nothing causes as much consternation as the sight of flowing blood, and there is usually present an irrepressible, almost involuntary, urge to staunch this leakage by whatever means available. Unfortunately under situations such as this the application of a tourniquet almost by historical precedence has become the standard procedure of choice. Without belaboring this criticism further, I cannot help but wonder about the number of limbs lost as a direct result of the injudicious application of this principle.

Fractures.—Management¹ of open or compound fracture of the extremities might well be divided into two basic phases; first, that applicable as the mission of the forward or combat zone and second, definitive care for which the base or general hospital must be responsible. The first phase mission is that of preventing infection and should be limited to thorough débridement or excision of the wound and adequate drainage, without closure, as well as immobilization, in order that pain and tissue damage may be minimized during transportation. Reduction should not be tried at this stage, and only gross malalignment is corrected at the time of splinting.

Devitalized tissues are excised in conjunction with liberal incisions of the skin and fascia, leaving in situ bone fragments with soft tissue attachments. These wounds are then left open unsutured and covered with petrolatum-impregnated fine mesh gauze. Tight packing of wounds is dangerous, but especially is this the case in wounds associated with fractures. Secondary closure of the wound uncomplicated by gross infection is usually performed four to six days after the initial débridement. This period may of necessity be prolonged in those soft tissue lacerations with or without underlying fractures where the evidence of gross infection remains obvious. One must remember that extension of the closure time beyond the six day period increases the fixation of the wound tissues and renders them less mobile and more difficult of apposition.

Methods of emergency splinting depend to a great extent on available facilities and individual preferences and, if adequate, do not necessarily adversely influence ultimate definitive therapy. The ideal transportation splint is the circular plaster cast, a method of equal value in the treatment of extensive soft tissue damage of the extremities without complicating fractures, when patients so afflicted must be transported with frequent handlings. Without exception every circular plaster cast, including the underlying sheet cotton padding, is split immediately after application.

The second phase in the care of the patient with an open fracture is the responsibility of the base or general hospital. Within a week after débridement, every plaster cast applied in the forward hospital is removed and the program of definitive care is initiated with the reduction and fixation of the fracture followed immediately or at an interval by a revision of the underlying wound. The

1. Hampton, O. P.: *Wounds of the Extremities in Military Surgery*, St. Louis, C. V. Mosby Company, 1951.

hanging cast or intramedullary nail affords a very acceptable mobile type of treatment for fractures of the humerus, whereas for fractures of the femoral shaft balanced suspension skeletal traction remains the most generally applicable method. However, intramedullary nailings of the broken femur even in the face of open wounds have yielded surprisingly good results in recent trials on our Korean casualties.

The intelligent primary management of the open wound of a joint is of *great significance in the final functional result* to be anticipated. Wide arthrotomy incision, through an area apart from the wound if indicated, with the excision of foreign bodies and devitalized articular cartilage and bone, followed by closure of the synovial membrane and capsule is the therapeutic method of choice. The remaining overlying soft tissues are closed secondarily several days later, as was discussed earlier. Immobilization of the joint is most important in the prevention of suppurative arthritis. The only joints left open for drainage are those hopelessly destroyed where one must anticipate a "frozen" functionless unit. In undébrided wounds of joints seen late and in established suppurative arthritis, the surgical procedure of choice remains the same, namely, intra-articular débridement and lavage, with closure of the synovial membrane and capsule. Needless to say the antibiotics play an important role in this therapeutic program.

There is no place for primary suture in the standard therapy of wounds of major peripheral nerve trunks, inasmuch as the definitive repair of severed nerves is not to be accomplished until the wound has healed and shown no evidence of infection for a period of at least three weeks. During the process of débridement nerve ends are neither to be tagged nor approximated by suture but rather are permitted to retract into protective soft tissue. Careful anatomical description of the findings at the original exploration are of inestimable value to the surgeon in the rear echelon of medical evacuation.

Wounds of major vessels of the extremities have always presented a serious problem to the military surgeon. Recent experiences in Korea are demonstrating the value of competent front line vascular surgical teams who with the use of both autogenous and homologous grafts have saved many limbs. Owing to the urgency of early and skilled care, such vascular wounds must have a high therapeutic priority. The accumulating rather favorable statistics may well lead to an acceptance of this apparent solution to an age-old problem as a standard approach to the care of wounds of major peripheral elements of the vascular system.

Amputation.—Early in World War II American forces accepted simple open circular amputation through the most distal level of viable tissue as the standard procedure of choice in the combat zone. The definitive plastic revision of the stump or reamputation at a more functional level was the responsibility of the rear fixed hospital. Once this method of standardized therapy became a routine order of procedure, many limbs and lives were saved. An integral, essential part of this treatment was the utilization of immediate and continuous skin traction plus the optimal splinting of the joint just proximal to the level of amputation.

BURNS

Among the many new problems that modern warfare has created for the military surgeon is that of large numbers of thermal burns, for combat techniques now include a great variety of situations that expose the participant directly to the actual flame. This difficulty is further compounded by the possibility of mass burn casualties over a relatively brief or almost instantaneous span of time. To appreciate the multiplicity of contributing factors, one has but to enumerate such relatively new instruments of war as the flame-thrower, napalm bomb, and atomic explosion, not to mention the constant dangers of such accidents as airplane crashes and fires aboard ship. Experiences from Hiroshima and Nagasaki have demonstrated the high incidence of thermal burns as a result of direct atomic flash exposure and of secondary fires.

The therapeutic challenge of burns has plagued military surgeons for many centuries, and it is only in very recent times that the seriously burned could be offered any hope of freedom from permanent disfigurement or of life itself. The great campaign surgeon Ambroise Paré writing in his diary gives us some insight into the hopelessness of the severely burned soldier in the 16th century. After describing the capture of a city he continues, "I entered a stable thinking to lodge my horse and that of my man, where I found four dead soldiers and three who were propped against the wall, their faces wholly disfigured, and they neither saw, nor heard, nor spoke, and their clothes yet flaming from the gunpowder which had burnt them. Beholding them with pity there came an old soldier who asked me if there was any means of curing them. I told him no. At once he approached them and cut their throats gently and without anger. Seeing this great cruelty, I said to him that he was a bad man. He answered me that he prayed God that when he should be in such a case, he might find someone who would do the same for him, to the end that he might not languish miserably."

The early management of the severely burned patient involves two major therapeutic phases, namely, the prevention and treatment of burn shock and the prevention of infection. The first phase must solve intelligently the problem of fluid and electrolyte balance, whereas the second phase, both by the use of aseptic techniques in handling of the open burn wound and by the maintenance of an adequate antibiotic blood level, must neutralize the hazards of infection. The later therapeutic procedures include skin grafting and other definitive plastic measures aimed at the total rehabilitation of the patient. Time does not permit an evaluation of the entire care of the burned patient. Inasmuch as the subject is standardization of therapeutic procedures, it might be well to direct attention to those facets that lend themselves to this approach and in which the ultimate definitive care might be jeopardized by inadequate or improper initial therapy.

Numerous formulas have been developed for the standardization of the approach to electrolyte and other blood-element imbalance precipitated by burn shock, most of which are calculated in relation to the percentage of total body surface burned. A simplified rule of nines

for an approximate estimation of the body area involved states that each of the upper extremities comprise 9% of body surface, the head and neck 9%, each lower extremity 18%, and the anterior and posterior aspects of the combined thoracoabdominal trunk each 18%. Any patient sustaining more than 20% surface burn is likely to go into some degree of shock and arbitrarily a 40% or more burn is considered as extensive and severe.

Evans² has developed a rather typical standard formula that when applied to a man weighing 70 kg. with a 35% burn calculates the first 24 hour fluid requirement as a total of 6,900 cc. broken down as follows: plasma, plasma expanders, or whole blood (70 by 35 by 1 cc.) 2,450 cc.; electrolyte solutions as isotonic sodium chloride (70 by 35 by 1 cc.) 2,450 cc.; and 5% glucose in water 2,000 cc. Half this amount of plasma and/or whole blood and electrolyte and the same amount (2,000 cc.) of 5% glucose in water is given the second 24 hours. The experience of the traumatic shock research team in Korea has shown that, when the use of plasma expanders is necessary, best results have been obtained by the administration of one unit of dextran with each unit of whole blood. A word of caution is indicated in the administration of large amounts of chloride in extensive burns, and rarely should more than 4,000 cc. of isotonic sodium chloride solution be given in the first 24 hours. The electrolyte balance of the burned patient can usually be stabilized after the first 48 hours by adequate amounts of fluid and food by mouth. The utilization of such a formula in no wise relieves the attending physician from the responsibilities of the application of good clinical judgment but does afford a degree of standardization that in the face of mass casualties and multiple evacuations more accurately regulates the therapeutic program.

The treatment of the burn wound itself commences with the prevention of further contamination. After the shock therapy is under way and clinical evaluation of the patient indicates that additional insults to the body economy will not precipitate further complications, under sterile aseptic technique the burned areas are gently but thoroughly cleansed and débrided. There are two major therapeutic measures advocated for the care of burn wounds, each having the support of highly qualified scientists. One is known as the occlusive pressure dressing method described by Allen and Koch³ and the other is the open or exposure treatment supported by Pulaski and his co-workers.⁴ Most forms of burn therapy are modifications of these basic concepts.

The closed treatment involves the application of sterile fine mesh gauze, either dry or petrolatum-impregnated, against the raw surface of the wound, over which is added mechanic's waste or absorbent cotton to afford pressure or absorb exudate. A final outer layer of dressing is applied so as to exert mild pressure to the underlying wound. Advocates of the closed method of treatment argue that after cleansing of the wound, further contamination is minimized, a certain degree of optimal splinting is afforded, and that patients are transportable.

The open or exposure method of therapy lends itself best to partial thickness burns involving only one side of the body and to burns of the head and buttocks. The fact that cooperation of the patient is essential limits to

some degree the application of this principle. One cannot help but be impressed by the role the exposure method of burn therapy may of necessity play in the event of large scale atomic attack where a limited supply of physicians may be called upon to handle thousands of severely burned patients. The many advantages that would accrue in the conservation of health personnel and time requirements under such a standard therapeutic procedure should not be underestimated.

ABDOMINAL WOUNDS

Though one cannot extrapolate combat statistics and apply them directly to expected atomic blast injuries, nevertheless certain valuable information can be gained from this experience.⁵ Approximately 4% of all those wounded in action sustain injury to the abdomen, with an over-all mortality rate in these cases of 35%; furthermore 85% of abdominal wounds penetrate the peritoneal cavity. The two major factors complicating wounds in this region are those of infection and hemorrhage, the former in the great majority of instances being secondary to perforation of the intestinal tract. Statistics show that, of all combat abdominal wounds, 20% will be penetration of the small intestine and some 10% of the large intestine. In instances of colon injury the mortality rate remains around 50%. It is standard procedure to explore every penetrating wound of the abdomen that cannot be proved to have missed the peritoneum.

The adoption of certain standard surgical measures in the face of perforations of the large intestine are essential to the proper management of this most serious category of intestinal wounds. To save life, the most important facet of therapy is that of short-circuiting the large intestine contents in order that the injured segment not be subjected to the trauma of distension and peristaltic action. In wounds involving less than half of the bowel circumference, one may perform either a simple loop colostomy using the injured loop or close the perforation and create a proximal colostomy. Where the wound is greater than half the circumference of the colon, the damaged portion is resected and a double barrel Mikulicz colostomy performed. Penetrating rectal and anal wounds, however innocuous they might appear, necessitate a laparotomy; should a perforation be discovered above the sphincter, a sigmoid colostomy is indicated. If at all possible, the wound area and operative incision are to be avoided as colostomy sites.

Injury to the liver is seen in 30% of combat abdominal wounds and carries with it a mortality rate of 18% if this is the sole viscus involved. Various methods of repair utilizing techniques of mattress sutures and absorbable packing are equally efficient; however, the damaged area is always drained. Unless this standard of procedure is studiously observed, a variety of complications secondary to bile and blood seepage are bound to occur.

4. Pulaski, E. J., and others: *Exposure (Open) Treatment of Burns*, U. S. Armed Forces M. J. 2: 769, 1951.

5. *Surgery of Trauma*, Bowers, W. F., editor, Philadelphia, J. B. Lippincott Company, 1953. Beebe, G. W., and De Bakey, M. E.: *Battle Casualties: Incidence, Mortality, and Logistic Considerations*, Springfield, Ill., Charles C Thomas, Publisher, 1952.

The spleen is injured in 7% of all combat abdominal wounds, though it is involved alone in only approximately 2% of cases. In the latter situation there is a mortality rate of 13%. The procedure of choice in all but superficial abrasions is immediate splenectomy, for temporizing may lead to delayed and fatal hemorrhage from a subcapsular hematoma.

Some 10% of those wounded in action sustain injuries of the chest. These combat statistics are expected to change as more experience is gained in the utilization of the armored vest. Thoracic wounds present a twofold problem, the first being that of a disturbed cardiorespiratory physiology and the second that of infection. The immediate and correct handling of chest wounds frequently spells the difference between life and death especially, as this pertains to the correction of respiratory imbalance. Open pneumothorax with the oft-described "sucking wound" necessitates prompt closure with a gauze compress or pack held in place by adhesive plaster. Suturing of such a wound preferably is delegated to a surgical team by whom adequate débridement and accurate closure can be accomplished.

Pressure pneumothorax is another complication of chest wounds requiring early attention. The relief of this situation is simple and effective if applied promptly and consists of the insertion into the pleural cavity of a catheter with a water seal valve or a needle with a rubber flutter valve. Repeated aspirations of the pleural cavity by a needle removing air and blood will aid in the maintenance of proper respiratory balance.

Supplementing the procedures directed at the specific situations described above are equally important therapeutic measures such as frequent tracheobronchial aspirations removing blood and mucous collections, administration of oxygen, transfusions when indicated, and the routine performance of tracheotomies in the unconscious patient with serious chest injury. Standardization of this early care has resulted in the saving of many lives and the improvement of morbidity rates.

Definitive care for the patient with a chest wound is carried out by competent thoracic teams not the least important member of which is a well-trained and efficient anesthesiologist. Blood clot and congealed purulent exudate that no longer yield to the aspirating needle will necessitate thoracotomy and decortication of the lung to permit satisfactory pulmonary expansion.

MAINTENANCE OF RECORDS

The absolute necessity for the maintenance of brief and yet accurate medical emergency records on all casualties is of paramount importance. To meet the standards of practicality such a system requires advance planning, simplicity in accomplishment, and the indoctrination of physicians as to the value of this procedure to the eventual welfare of the patient. Anyone who has functioned as a medical officer in the chain of patient evacuation will attest to the sense of therapeutic frustration developed by inadequate recordings of emergency care. In the event of radiation exposure, there are additional data that only the person administering initial care will be able to record with any degree of accuracy. Among these is the geographic relationship to ground zero at the time of exposure.

SUMMARY

The purpose of this paper is to present certain qualifying factors that modify the application of medicine to combat or catastrophic situations and to point out the possible benefits that will accrue as civilian physicians share the experiences of the armed forces in medical organization applicable to the care of mass casualties.

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. STORMONT, M.D., Secretary.

Tetraethylammonium Chloride.—Etamon Chloride (Parke, Davis).— $C_2H_5)_4N \cdot Cl$.—M.W. 165.71.—Tetraethylammonium chloride is made in the form of a 50% solution in water. From this solution the dosage forms are prepared. The structural formula of tetraethylammonium chloride may be represented as follows:

Actions and Uses.—Tetraethylammonium chloride is a quaternary ammonium compound belonging to a class of drugs that, like nicotine and curare, act as generalized ganglionic blocking agents. The drug partially blocks transmission of motor nerve impulses through the ganglia of both the sympathetic and parasympathetic divisions of the autonomic nervous system. Its action is not adrenolytic and is interrupted by neostigmine. The blocking of sympathetic stimuli associated with vasospasm usually results in an increased blood supply to the affected region, accompanied by reduction in arterial pressure due to vasodilation. The simultaneous interference with the transmission of parasympathetic impulses produces loss of ocular accommodation, cessation or decrease of motility of the gastrointestinal tract, and alteration of urinary bladder function.

Tetraethylammonium chloride is of limited clinical usefulness as a therapeutic and diagnostic agent in the management of peripheral vascular diseases and other conditions involving vascular dysfunction. It has been employed successfully in the therapy of thromboangiitis obliterans (Buerger's disease), arteriosclerosis obliterans, various causalgias including reflex dystrophy, herpes zoster, thrombophlebitis, Raynaud's disease, acrocyanosis, trenchfoot, and immersion foot. It may be employed diagnostically in acrovacular conditions to estimate the contribution of sympathetic stimuli in the maintenance of vasospasm.

Tetraethylammonium chloride promptly lowers blood pressure in both normal and hypertensive patients. Peripheral circulatory collapse has followed its use. Patients occasionally also experience dyspnea with hyperventilation, weakness, fatigue, lightheadedness, slowing of speech, dulling of the sensorium, difficulty in muscle movement that is not associated with impairment of the deep reflexes, dryness of the mouth, and loss of ocular accommodation. The drug should be employed with caution in patients with severe hypertension, particularly in the presence of poor renal function or high diastolic blood pressure. Repeated administration should be avoided in the presence of impaired renal excretion. Tetraethylammonium chloride is not suitable for the treatment of hypertension because its hypotensive effect is not sustained. It

should not be used in patients with recent coronary thrombosis and should be used with caution in all elderly patients and those with arteriosclerosis because they often experience unusual decrease in blood pressure with diminution in blood flow through the extremities.

Dosage.—Tetraethylammonium chloride is administered by intravenous or intramuscular injection. Intramuscular injection produces local tenderness and burning. Subcutaneous injection produces considerable local irritation and oral administration is ineffective.

The intravenous dose is 2 to 5 cc. of a solution representing 0.2 to 0.5 gm. (not to exceed 7 mg. per kilogram of body weight). Frequency of injection depends on duration of relief of symptoms. The effectiveness of the dose can be judged properly only on the basis of three or more injections. Injections may be given once or twice daily for several weeks in exceptional cases. The effects of the drug appear almost immediately after intravenous administration and postural hypotension lasts from several minutes to one hour. Patients should be kept recumbent for at least one hour after intravenous injection.

The intramuscular dose is 10 to 12 cc. (5 to 6 cc. in each buttock) of the same concentration as that used intravenously, representing 1 to 1.2 gm. (not to exceed 20 mg. per kilogram of body weight). This maintains an effective sympathetic block for 6 to 36 hours in hospitalized patients. Continuation of the autonomic blockade for longer than 36 hours usually causes considerable distress. Addition of 1 cc. of 2% procaine hydrochloride solution to the dose of tetraethylammonium chloride decreases the discomfort caused by intramuscular injection.

Peripheral circulatory collapse should be treated by artificial respiration and/or injection of epinephrine hydrochloride solution 1:1,000. Intravenous administration of 0.5 to 1 mg. of neostigmine methylsulfate in solution antagonizes the blocking action of tetraethylammonium chloride and promotes rapid recovery from the postural hypotension.

Tests and Standards.—

The following tests and standards apply to the 50% aqueous solution of tetraethylammonium chloride.

Physical Properties: Tetraethylammonium chloride, isolated by evaporating the 50% solution in a vacuum, is an extremely hygroscopic, odorless, white solid. It is very soluble in water and in alcohol, freely soluble in chloroform, and practically insoluble in benzene and in ether. The pH of the 50% solution is 5.8 to 6.5.

Identity Tests: To 1 ml. of the 50% solution of tetraethylammonium chloride add 10 ml. of water, 0.5 ml. of diluted nitric acid, and 1 ml. of silver nitrate T.S.: a white precipitate forms that dissolves in 10 ml. of ammonium hydroxide T.S. (presence of chloride).

Shake about 1 gm. of ammonium reineckate with 25 ml. of water. Filter the mixture and add 5 ml. of the clear solution to 5 ml. of the 50% solution of tetraethylammonium chloride: a pink precipitate forms.

To 3 ml. of the 50% solution of tetraethylammonium chloride add 10 ml. of a saturated alcoholic solution of picric acid (1 gm. in 12 ml.): a fine, yellow, crystalline precipitate forms. Filter the mixture and wash the precipitate with 3 ml. of isopropyl alcohol and dry it at 105° for 4 hours: the picrate obtained melts (Caution! May be explosive. Use safety glass shield) with decomposition at 257-260°.

Purity Tests: The amount of triethylamine hydrochloride found in the assay is not more than 0.5%.

With water dilute to 50 ml. exactly 1 ml. of the 50% solution of tetraethylammonium chloride and on this solution run a U. S. P. heavy metals test: the amount of heavy metals does not exceed 20 ppm.

Evaporate in a platinum crucible 2 ml., accurately measured, of the 50% solution of tetraethylammonium chloride. Carefully ignite, cool, and weigh: the residue does not exceed 0.1%.

Assay: (Tetraethylammonium Chloride) Accurately measure into a 200 ml. volumetric flask 1 ml. of the 50% solution of tetraethylammonium chloride, and add 50 ml. of water and exactly 50 ml. of 0.1 N silver nitrate. Acidify the mixture with 3 ml. of nitric acid, agitate it until the precipitate coagulates and the supernatant liquid is clear, dilute to the mark with water, and mix. Filter the mixture through dry filter paper. Discard the first 20 ml. of filtrate and titrate exactly 100 ml. of the subsequent filtrate with 0.1 N potassium thiocyanate, using 2 ml. of ferric ammonium sulfate T.S. as an indicator. Each milliliter of 0.1 N silver nitrate consumed is equivalent to 0.003546 gm. of chloride and to 0.01657 gm. of tetraethylammonium chloride plus triethylamine expressed as tetraethylammonium chloride (total amines).

Accurately measure into a 400 ml. beaker 10 ml. of the 50% solution of tetraethylammonium chloride and dilute it with 190 ml. of alcohol. Run a potentiometric titration with 0.1 N sodium hydroxide, using a glass electrode. Run a blank titration on 190 ml. of alcohol. Each milliliter of 0.1 N sodium hydroxide consumed is equivalent to 0.01376 gm. of triethylamine hydrochloride that in turn is equivalent to 0.01656 gm. of tetraethylammonium chloride.

Subtract the amount of tetraethylammonium chloride equivalent to the triethylamine from the value for total amines to get the amount of

tetraethylammonium chloride itself. The amount of tetraethylammonium chloride is not less than 47.5 nor more than 52.5%, equivalent to not less than 95.0 or more than 105.0% of the labeled amount of tetraethylammonium chloride.

Dosage Forms of Tetraethylammonium Chloride

SOLUTIONS. Physical Properties: The pH of the 10% solution is 5.8 to 6.5.

Identity Tests: The solution responds to the reineckate and picrate identity tests for the 50% solution in the monograph for tetraethylammonium chloride.

Assay: (Tetraethylammonium Chloride) Transfer to a 200 ml. volumetric flask a volume of solution, accurately measured, equivalent to about 0.5 gm. of tetraethylammonium chloride. Add 50 ml. of water and exactly 50 ml. of 0.1 N silver nitrate. Proceed as directed in the assay for the 50% solution in the monograph for tetraethylammonium chloride starting with, "Acidify the mixture with 3 ml. of nitric acid, agitate it until the precipitate coagulates . . ." Each milliliter of 0.1 N silver nitrate consumed is equivalent to 0.01657 gm. of tetraethylammonium chloride (total amines).

Transfer to a 400 ml. beaker a volume of solution, accurately measured, equivalent to about 5 gm. of tetraethylammonium chloride and dilute it with 190 ml. of alcohol. Run a potentiometric titration with 0.1 N sodium hydroxide, using a glass electrode. Run a blank titration on 190 ml. of alcohol. Each milliliter of 0.1 N sodium hydroxide consumed is equivalent to 0.01376 gm. of triethylamine hydrochloride, which in turn is equivalent to 0.01656 gm. of tetraethylammonium chloride.

Subtract the amount of tetraethylammonium chloride equivalent to the triethylamine hydrochloride from the value for total amines to get the amount of tetraethylammonium chloride itself. The amount of tetraethylammonium chloride is not less than 95.0 or more than 105.0% of the labeled amount.

Parke, Davis & Company, Detroit.

Solution Etamon Chloride 10%: 20 cc. Steri-Vials. A solution containing 0.1 gm. of tetraethylammonium chloride in each cubic centimeter. Preserved with 0.005% benzethonium chloride. U. S. trademark 432,476.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

APPARATUS ACCEPTED

The following additional product has been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

RALPH E. DE FOREST, M.D., Secretary.

M. H. E. Refrigeratic Oxygen Tents, Models RV-2 and RV-3 Modern Hospital Equipment, Inc., 119 N. Fourth St., Minneapolis 1.

The M. H. E. Refrigeratic Oxygen Tent consists of two principal parts: a canopy of transparent material to be suspended over the patient's bed and a cabinet housing the machinery for humidifying, cooling, and circulating the oxygen.

The cabinet is mounted on large casters so that it can be rolled alongside the bed; it measures 84 (height) by 71 by 46 cm. (33 by 28 by 18 in.). Model RV-2 weighs 87 kg. (191 lb.); Model RV-3 weighs 93 kg. (206 lb.).

The models differ in the motor-compressor units. Model RV-2 has a one-fifth horsepower compressor, and its motor draws 650 watts. Model RV-3 has a one-third horsepower compressor, and its motor draws 860 watts. Both units require a source of 60 cycle alternating current at 115 volts. The shipping weights for Models RV-2 and RV-3 are 107 and 113 kg. (235 and 250 lb.), respectively.

Evidence indicating sound construction and satisfactory performance was obtained from sources acceptable to the Council.

M. H. E. Refrigeratic Oxygen Tent, Model RV-2

THE HAND AND CARDIOVASCULAR DISEASE

Despite widespread and sometimes unnecessary use of numerous laboratory tests in day-by-day clinical practice, diagnostic methods that require no special apparatus and that depend only on simple observation can play an effective role in obtaining clinical information about patients. In this connection, the human hand is a unique organ from which an extraordinary amount of clinical information may be derived. According to Silverman and Littman,¹ examination of the hand will often disclose interesting and occasionally revealing information about the cardiovascular status of patients. In a general way, the size of the hand is proportional to the rest of the body, and a rough approximation of the cardiac silhouette is obtained by examination of the size of the fist.² Under normal conditions the outline of the fist and the orthodiagraphic silhouette coincide, a small fist usually indicating a small heart.

Excessive palmar sweating constitutes one of the more striking findings in neurocirculatory asthenia. Sweating of the palms reflects emotional activities; it is increased during tension and excitement, although some degree of palmar sweating does occur in normal persons who are in a state of anticipation. A tremor of wide amplitude may also be detected in patients afflicted with neurocirculatory asthenia. The combination of excessive palmar sweating and a pronounced tremor of the outstretched fingers is a frequent finding in neurocirculatory asthenia and almost never takes place in normal persons.

Cyanosis and clubbing of the fingers have long been associated with congenital heart disease. Clubbing of the

fingers does not appear at birth and very rarely before the age of 2 years; however, when congenital heart disease is suspected, alert clinicians search for associated congenital anomalies. Polydactyly and syndactyly, for example, may be associated with congenital heart disease. Moreover, arachnodactyly, which is characterized by abnormally long, slender fingers, is a hereditary disorder in which there is a high incidence of cardiovascular anomalies, including septal defects, vascular hypoplasia, and medionecrosis of the aorta.

Study of the hand is especially rewarding in the case of subacute bacterial endocarditis. Diagnosis of this disease is sometimes established initially by information supplied solely by the hand. According to Libman,³ a diagnostic sign pathognomonic of subacute bacterial endocarditis is supplied by the so-called Osler node, which consists of a small, tender red nodule located in the pads of the finger or in the thenar or hypothenar eminences. Pallor is a more or less constant finding in subacute bacterial endocarditis; the degree of pallor can be determined by observing the color of the palms. Wintrobe⁴ asserts that the palmar site is more reliable for judging pallor than mucous membranes or conjunctivas.

A clue to the existence of endocrine disturbances is also supplied by the hand. In hyperthyroidism, the hands are tremulous, flushed warm and moist, with the skin smooth and satiny; in hypothyroidism, the hands are dry, rough, and cold. The hand of a cretin is characteristically underdeveloped, while the hand of an acromegalic person is large, broad, and usually coarse and swollen.

The shoulder-hand syndrome is a disabling complication of myocardial infarction, which is characterized initially by a great deal of pain, stiffness, and limitation of motion of the shoulder joint and girdle, and is followed by involvement of the hands and fingers. Two signs of the hand suggestive of disturbance in liver function are thought to occur: erythema of the palms and spider angiomas or pulsating vascular nevi. Raynaud's syndrome primarily involves the fingers, while in advanced congestive heart failure the hands are invariably cold, the veins on the dorsum engorged, and the finger-nail-bed cyanotic.

Finally, it should be pointed out that the hands are admirably suited for study of the dynamics of peripheral circulation.⁵ As a matter of practical importance, the color and temperature of the skin of the hands sometimes yield more information of impending shock than either the pulse or the blood pressure. Indeed, a warm, pale hand abruptly changing in appearance during illness to a cold, deeply colored, cyanotic state supplies dramatic evidence of peripheral circulatory failure.

CHILDREN AS SURGICAL PATIENTS

The reactions of children who become surgical patients in a hospital for the first time vary considerably. Older children, especially those over 5 years of age, seem to forget the stay in a hospital quickly, while those under 5 years are more likely to show transient behavior changes—fear of the dark, fear of being left alone, and such regressive behavior phenomena as bed wetting, wanting to be fed, and fear of doctors and nurses. Disobedience, temper tantrums, increasing dependency, and spiteful, defiant behavior are more likely to occur in older children.

According to Mac Keith,¹ the three principal anxieties that concern children who are admitted to a hospital for the first time deal with separation from the home, the nature of the anesthetic, and the operation itself. While older children usually regard separation from a home environment to be temporary, younger children occasionally react in a highly charged manner. Very young children sometimes feel so lonely and deserted that they do not appear to pay too much attention to the operation itself; this is true of children who remain in a hospital environment for a period longer than was originally anticipated. In some instances, children develop fantastic notions about operative and anesthetic procedures and display unrestrained consternation regarding what will be done to them while they are under the influence of an anesthetic agent.

In the case of tonsillectomy, Coleman² proposes that a child who is to be subjected to this procedure be given a forthright explanation of the reasons for the operation; that a recognizable word-picture be drawn of the hospital, the operation, the nurse, and doctors; that an explanation be made, pointing out that the purpose of anesthesia is to relieve the child of pain during the operation; and that the parents be urged to reassure the child and display affection for him during the post-operative period. Before the operation, a very young child who brings along a familiar toy, a pair of slippers, or a pillow on admission to the hospital creates a tangible tie with his home. The admittance of a child to a hospital some 24 hours before an operation will often enable him to overcome a sense of initial panic and thereby afford him an opportunity to establish amicable relations with his fellow patients and with nurses and doctors.

Parents can play an extremely important role in preparing the child psychologically and emotionally before admission to the hospital. Actually, it is important that all three—mother, father, and child—know in a general way what will ensue in the hospital. The parents should possess sufficient information in order to answer those questions the child is certain to ask. Parents, and mothers particularly, need guidance in preparing a child for a hospital experience. A gigantic step forward in terms of parental education could be taken if the medical profession together with hospitals would routinely issue instructional leaflets to parents of children who are about to become surgical patients.

NOCTURNAL ENURESIS

Enuresis is a major problem, involving about 16% of the population between the ages 3 to 15 years. A solution is necessary for the social adjustment of the child, and those few persons in whom enuresis persists into adult life are truly handicapped. Anatomic or physiological abnormalities are present in only about 3% of those affected,¹ and since these can be treated by specific measures they do not enter into the present discussion. In any child, if bladder control is not accomplished by the time he has reached the age of 3½ years, training is likely to be difficult.

The causes proposed for nocturnal enuresis are varied and range from laziness to psychic disturbances. Holt and Holland state that bedwetting is purely a habit often associated with other habits that go with an unstable personality. Grulee and Eley say that a strong familial tendency is commonly observed in these patients and that they maintain an irritable bladder throughout life even though they are no longer enuritic. Turton and Spear² obtained electroencephalograms on 100 enuritic children and found 22 with epileptiform tracings, 28 with immature tracings, and 23 whose tracings were on the borderline of abnormality. They concluded that many enuritics who do not respond to treatment have an unsuspected physical basis for their disorder and that the electroencephalogram is of aid in the diagnosis.

Because the desire to urinate depends on the pressure within the bladder rather than on the amount of fluid O'Malley and Owens³ used methantheline (Banthine) to inhibit the local reflex vesical spasm and found that with this treatment the bladder could accommodate more fluid without an increase in intravesicular pressure. A noteworthy concomitant of this treatment was the psychological relief and increased self-confidence of the child. Some of their patients required a second course of the drug, but none required a third course.

Geppert,¹ on the other hand, has had successful results in 91% of a series of 42 children treated by conditioned response after restriction of fluid intake and rewards had failed. The method is cumbersome in that it requires special equipment and its success depends on careful observation of the details of the technique and close supervision by the parents. The patient sleeps on a moisture sensitive bed pad that is connected to an electric alarm. A moist spot the size of a silver dollar will set off the alarm. The child must be thoroughly awakened and must empty his bladder. The pad must then be replaced with a dry one and the alarm reset. The author found that sporadic bedwetters were the slowest to respond and that their progress was hardest to gauge. The chief cause of failures was poor parental cooperation.

CHILDREN AS SURGICAL PATIENTS

The reactions of children who become surgical patients in a hospital for the first time vary considerably. Older children, especially those over 5 years of age, seem to forget the stay in a hospital quickly, while those under 5 years are more likely to show transient behavior changes—fear of the dark, fear of being left alone, and such regressive behavior phenomena as bed wetting, wanting to be fed, and fear of doctors and nurses. Disobedience, temper tantrums, increasing dependency, and spiteful, defiant behavior are more likely to occur in older children.

According to Mac Keith,¹ the three principal anxieties that concern children who are admitted to a hospital for the first time deal with separation from the home, the nature of the anesthetic, and the operation itself. While older children usually regard separation from a home environment to be temporary, younger children occasionally react in a highly charged manner. Very young children sometimes feel so lonely and deserted that they do not appear to pay too much attention to the operation itself; this is true of children who remain in a hospital environment for a period longer than was originally anticipated. In some instances, children develop fantastic notions about operative and anesthetic procedures and display unrestrained consternation regarding what will be done to them while they are under the influence of an anesthetic agent.

In the case of tonsillectomy, Coleman² proposes that a child who is to be subjected to this procedure be given a forthright explanation of the reasons for the operation; that a recognizable word-picture be drawn of the hospital, the operation, the nurse, and doctors; that an explanation be made, pointing out that the purpose of anesthesia is to relieve the child of pain during the operation; and that the parents be urged to reassure the child and display affection for him during the post-operative period. Before the operation, a very young child who brings along a familiar toy, a pair of slippers, or a pillow on admission to the hospital creates a tangible tie with his home. The admittance of a child to a hospital some 24 hours before an operation will often enable him to overcome a sense of initial panic and thereby afford him an opportunity to establish amicable relations with his fellow patients and with nurses and doctors.

Parents can play an extremely important role in preparing the child psychologically and emotionally before admission to the hospital. Actually, it is important that all three—mother, father, and child—know in a general way what will ensue in the hospital. The parents should possess sufficient information in order to answer those questions the child is certain to ask. Parents, and mothers particularly, need guidance in preparing a child for a hospital experience. A gigantic step forward in terms of parental education could be taken if the medical profession together with hospitals would routinely issue instructional leaflets to parents of children who are about to become surgical patients.

NOCTURNAL ENURESIS

Enuresis is a major problem, involving about 16% of the population between the ages 3 to 15 years. A solution is necessary for the social adjustment of the child, and those few persons in whom enuresis persists into adult life are truly handicapped. Anatomic or physiological abnormalities are present in only about 3% of those affected,¹ and since these can be treated by specific measures they do not enter into the present discussion. In any child, if bladder control is not accomplished by the time he has reached the age of 3½ years, training is likely to be difficult.

The causes proposed for nocturnal enuresis are varied and range from laziness to psychic disturbances. Holt and Holland state that bedwetting is purely a habit often associated with other habits that go with an unstable personality. Grulee and Eley say that a strong familial tendency is commonly observed in these patients and that they maintain an irritable bladder throughout life even though they are no longer enuritic. Turton and Spear² obtained electroencephalograms on 100 enuritic children and found 22 with epileptiform tracings, 28 with immature tracings, and 23 whose tracings were on the borderline of abnormality. They concluded that many enuritics who do not respond to treatment have an unsuspected physical basis for their disorder and that the electroencephalogram is of aid in the diagnosis.

Because the desire to urinate depends on the pressure within the bladder rather than on the amount of fluid O'Malley and Owens³ used methantheline (Banthine) to inhibit the local reflex vesical spasm and found that with this treatment the bladder could accommodate more fluid without an increase in intravesicular pressure. A noteworthy concomitant of this treatment was the psychological relief and increased self-confidence of the child. Some of their patients required a second course of the drug, but none required a third course.

Geppert,¹ on the other hand, has had successful results in 91% of a series of 42 children treated by conditioned response after restriction of fluid intake and rewards had failed. The method is cumbersome in that it requires special equipment and its success depends on careful observation of the details of the technique and close supervision by the parents. The patient sleeps on a moisture sensitive bed pad that is connected to an electric alarm. A moist spot the size of a silver dollar will set off the alarm. The child must be thoroughly awakened and must empty his bladder. The pad must then be replaced with a dry one and the alarm reset. The author found that sporadic bedwetters were the slowest to respond and that their progress was hardest to gauge. The chief cause of failures was poor parental cooperation.

ORGANIZATION SECTION

LEGISLATIVE REVIEW

(First Session, 83rd Congress)

Following is a résumé of the major legislative measures with medical implications that were introduced during the first session of the 83rd Congress. Identical House and Senate bills have not been indicated. The listing, which shows the bill numbers, authors, interested congressional committees, purposes, and position of the American Medical Association, if any, has been broken down under the following general subjects: (1) members of armed services and their dependents, (2) veterans and veterans administration, (3) medical research and establishment of medical foundation, (4) federal subsidization of educa-

tion, (5) tax relief, (6) social security and disability insurance, (7) federal subsidization of private health insurance plans, (8) aid to the handicapped, and (9) miscellaneous. The action indicated in the last column is that taken by the Board of Trustees unless otherwise specified. Action by the Committee on Legislation is indicated when taken too recently for confirmation by the Board of Trustees. If additional information concerning the purposes of these bills or the basis for the position adopted by the Association is desired, a request should be addressed to the Committee on Legislation, 535 North Dearborn Street, Chicago 10, Ill.

C. JOSEPH STETLER, Secretary.

Members of Armed Services and Their Dependents

Bill No.	Introduced by	Congressional Committee	Subject or Purpose	Association Action and Date
S. 33	McCarran, Nev.	Armed Services, Senate	To provide hospitalization and medical care for members of Coast Guard and their dependents in military facilities	Opposition (active) 4/26/53
S. 70 *	Young, N. D.	Armed Services, Senate	To allow credit under "Doctor-Draft" law for service with countries that were allies of U.S. during World War II	Approval (active) 2/6/53
S. 1491	Potter, Mich.	Armed Services, Senate	Crediting internment time during World War II for purposes of "Doctor-Draft" law	No action 6/4/53
S. 1495	Murray, Mont.	Labor and Public Welfare, Senate	Emergency maternity and infant care program	Opposition (active) 6/4/53
S. 1531 †	Saltonstall, Mass., and Hunt, Wyo.	Armed Services, Senate	Amend and extend "Doctor-Draft" law	Approval, with amendments, 4/26/53
S. 1531 * Amendment	Hunt, Wyo.	Armed Services, Senate	Amendment to "Doctor-Draft" law re extension of \$100 per month "special pay"	
H.R. 97 *	Burdick, N. D.	Armed Services, H.R.	To allow credit under the "Doctor-Draft" law for service with countries that were allies of U. S. during World War II	Approval (active) 4/26/53
H.R. 173	Rivers, S. O.	Armed Services, H.R.	To provide hospitalization and medical care for dependents of members of armed services in military facilities	Opposition (active) 2/6/53
H.R. 2452	Boggs, La.	Armed Services, H.R.	Dispensary treatment and hospitalization for retired enlisted military personnel in military installations	Opposition (active) 4/26/53
H.R. 2756	Seely-Brown, Conn.	Armed Services, H.R.	To provide hospitalization and medical care for members of Coast Guard and their dependents in military facilities	Opposition (active) 4/26/53
H.R. 2955 *	Judd, Minn.	Armed Services, H.R.	To allow credit under "Doctor-Draft" law for previous service in nonmedical status	Approval (active) 4/26/53
H.R. 4200	Budge, Idaho	Armed Services, H.R.	Crediting internment time during World War II for purposes of "Doctor-Draft" law	No action 6/4/53
H.R. 4447	Bolton, Ohio	Armed Services, H.R.	Appointment of male nurses in U. S. Army Reserve	No action 6/4/53
H.R. 4495 †	Short, Mo.	Armed Services, H.R.	Amend and extend "Doctor-Draft" law	Approval, with amendments, 4/26/53
H.R. 4642	Bosch, N. Y.	Armed Services, H.R.	Emergency maternity and infant care	Opposition (active) 6/4/53
H.R. 5017	Short, Mo.	Armed Services, H.R.	Appointment of osteopaths in Medical Corps of Army, Navy, and Air Force	Opposition 10/22/53

Veterans and Veterans Administration

S. 370	Murray, Mont.	Labor and Public Welfare, Senate	Construction of additional Veterans Administration hospitals	Opposition (active) 4/26/53
S. 609	Sparkman, Ala.	Finance, Senate	Presumption of service connection for chronic and tropical diseases	Opposition (active) 4/26/53
S. 762	Martin, Pa.	Finance, Senate	Presumption of service connection for tuberculosis, multiple sclerosis, and psychosis	Opposition (active) 4/26/53
S. 1063	Griswold, Neb., and Ives, N. Y.	Labor and Public Welfare, Senate	Hospital care and medical treatment for veterans residing abroad	Opposition 6/4/53
H.R. 25	Rogers, Mass.	Veterans' Affairs, H.R.	Presumption of service connection for chronic and tropical diseases	Opposition (active) 4/26/53
H.R. 29	Rogers, Mass.	Veterans' Affairs, H.R.	Construction of additional Veterans Administration hospitals	Opposition (active) 4/26/53
H.R. 33	Rogers, Mass.	Veterans' Affairs, H.R.	Presumption of service connection for tuberculosis, psychosis, and multiple sclerosis	Opposition (active) 4/26/53
H.R. 35	Rogers, Mass.	Veterans' Affairs, H.R.	Hospital care and medical treatment for disabled veterans visiting or residing abroad	Opposition 4/26/53
H.R. 45	Rogers, Mass.	Veterans' Affairs, H.R.	Presumption of service connection for malignant tumors	Opposition (active) 4/26/53
H.R. 46	Rogers, Mass.	Veterans' Affairs, H.R.	Presumption of service connection for tuberculosis for World War II veterans	Opposition (active) 4/26/53
H.R. 54	Rogers, Mass.	Veterans' Affairs, H.R.	To authorize appointment of chiropractors in Veterans Administration	Opposition (active) 4/26/53
H.R. 333	Rogers, Mass.	Veterans' Affairs, H.R.	To authorize outpatient treatment by Veterans Administration for non-service-connected disabilities	Opposition (active) 4/26/53
H.R. 1414	Rogers, Mass.	Veterans' Affairs, H.R.	To provide interchange of hospital facilities between Veterans Administration and Department of Defense	Approval 4/26/53

* Subject of bill included in Public Law 84, 83rd Congress, June 29, 1953.

† Identical with H.R. 4495 enacted into Public Law 84, 83rd Congress, June 29, 1953.

‡ Enacted into Public Law 84, 83rd Congress, June 29, 1953.

Veterans and Veterans Administration—Continued

Bill No.	Introduced by	Congressional Committee	Subject or Purpose	Association Action and Date
H.R. 2097	Hagen, Minn.	Veterans' Affairs, H.R.	Presumption of service connection for pulmonary tuberculosis	Opposition (active) 4/26/53
H.R. 2573	Rogers, Mass.	Veterans' Affairs, H.R.	Extension of hospital care for veterans of Spanish-American War	Opposition (active) 4/26/53
H.R. 2980	Rogers, Mass.	Veterans' Affairs, H.R.	To authorize appointment of optometrists in Veterans Administration	Opposition 4/26/53
H.R. 3070	Frellinghuysen, N. J.	Veterans' Affairs, H.R.	Presumption of service connection for amyotrophic lateral sclerosis	Opposition (active) 4/26/53
H.R. 4601	Teague, Texas	Veterans' Affairs, H.R.	Amendment to law authorizing hospitalization and medical care for veterans with non-service-connected disabilities	Opposition (active) 6/4/53
H.R. 5012	McCarthy, Minn.	Veterans' Affairs, H.R.	Presumption of service connection for pulmonary tuberculosis and multiple sclerosis	Opposition (active) 10/22/53
H.R. 5636 §	Radwan, N. Y.	Veterans' Affairs, H.R.	Presumption of service connection for all types of tuberculosis	
H.R. 5892	Rogers, Mass.	Veterans' Affairs, H.R.	To increase federal contribution to state and territorial homes for veterans' care	Opposition (active) 10/22/53
H.R. 5893	Rogers, Mass.	Veterans' Affairs, H.R.	Medical care for retired military personnel	Approval 10/22/53
H.R. 6016	Teague, Texas	Veterans' Affairs, H.R.	Amend existing law relative to hospitalization and medical care of veterans	Opposition 10/22/53
H.Res. 140	Kelly, N. Y.	Rules, H.R.	Investigation of Veterans Administration	Approval (active) 4/26/53
Medical Research and Establishment of Medical Foundation				
S. 156	Langer, N. D.	Labor and Public Welfare, Senate	Establishment of National Epilepsy Institute	Opposition (active) 4/26/53
S. 188	Neely, W. Va.	Labor and Public Welfare, Senate	Federal subsidization of cancer research	Opposition (active) 4/26/53
S. 977 †	Smith, N. J., and Alken, Vt.	Labor and Public Welfare, Senate	Provision of additional funds to National Science Foundation	
H.R. 563	Rooney, N. Y.	Foreign Affairs, H.R.	Federal subsidization of cancer research	Opposition (active) 4/26/53
H.R. 2290	Morrison, La.	Interstate and Foreign Commerce, H.R.	Establishment of National Institute for Polio-myelitis	Opposition (active) 4/26/53
H.R. 4689 ¶	Wolverton, N. J.	Interstate and Foreign Commerce, H.R.	To amend the National Science Foundation Act of 1950	
H.J.Res. 166	Hinshaw, Calif.	Rules, H.R.	Establishment of Joint Committee on Science	No action 4/26/53
H.Res. 286	Metcalf, Mont.	Rules, H.R.	To study ways of preventing and controlling silicosis	No action 10/22/53
Federal Subsidization of Education				
S. 461	Humphrey, Minn.	Labor and Public Welfare, Senate	Federal aid for public health education	Opposition (active) 4/26/53
S. 1515 ‡	Hunt, Wyo., and 11 other Senators	Labor and Public Welfare, Senate	Establishment of Western Interstate Commission for higher education	
S. 2168	Langer, N. D.	Labor and Public Welfare, Senate	College scholarship loans	Opposition (active) 10/22/53
H.R. 250	Elliott, Ala.	Education and Labor, H.R.	Federal aid to health and safety instruction and physical education in public elementary and secondary schools	Opposition (active) 4/26/53
H.R. 1240	Cole, N. Y.	Armed Services, H.R.	To establish cadet nurse programs	Opposition 12/3/53 (Committee on Legislation)
H.R. 2718	Heller, N. Y.	Interstate and Foreign Commerce, H.R.	Creation of U. S. Medical and Dental Academy	Opposition (active) 4/26/53
H.R. 2838	Elliott, Ala.	Education and Labor, H.R.	Federal aid in fields of higher education	Opposition (active) 4/26/53
H.R. 3850	Bolton, Ohio	Interstate and Foreign Commerce, H.R.	Federal aid to nursing education	Opposition 10/22/53
H.R. 6079	Boland, Mass.	Education and Labor, H.R.	College scholarship fund	Opposition (active) 10/22/53
Tax Relief				
S. 898	Johnson, Colo.	Finance, Senate	Tax relief for permanently and totally disabled	No action 4/26/53
S. 1154	Ives, N. Y., and Flanders, Vt.	Finance, Senate	Provide for deduction of health insurance premiums for income tax purposes	Opposition 6/4/53
H.R. 10	Jenkins, Ohio	Ways and Means, H.R.	Postponement of tax payments on amounts used to purchase retirement annuities	Approval (active) 2/6/53
H.R. 11	Keogh, N. Y.	Ways and Means, H.R.	Postponement of tax payments on amounts used to purchase retirement annuities	Approval (active) 2/6/53
H.R. 474	Keating, N. Y.	Ways and Means, H.R.	Deduction of medical expenses for income tax purposes	Approval (active) in principle, 4/26/53
H.R. 482	Keating, N. Y.	Ways and Means, H.R.	Provide deduction of health insurance premiums for income tax purposes	Approval in principle 4/26/53
H.R. 1029	Hand, N. J.	Ways and Means, H.R.	Provide deduction of health insurance premiums for income tax purposes	No action 4/26/53
H.R. 1725	Rhodes, Pa.	Ways and Means, H.R.	Tax relief for permanently and totally disabled	No action 4/26/53
H.R. 2243	Dague, Pa.	Ways and Means, H.R.	Removal of 5% limitation on medical expense deductions from income tax	Approval (active) in principle, 4/26/53
H.R. 3375	Matthews, Fla.	Ways and Means, H.R.	Removal of 5% limitation on medical expense deductions for income tax purposes	Approval (active) in principle, 6/4/53
H.R. 3583	Hale, Maine	Ways and Means, H.R.	Provide for deduction of health insurance premiums for income tax purposes	Opposition 6/4/53
H.R. 3585	Javits, N. Y.	Ways and Means, H.R.	Provide for deduction of health insurance premiums for income tax purposes	Opposition 6/4/53
H.R. 3911	Bolton, Ohio	Ways and Means, H.R.	Removal of limitation on medical expense deductions for income tax purposes	Approval (active) in principle, 6/4/53
H.R. 4393	Davis, Ga.	Ways and Means, H.R.	Professional education expense deductions for income tax purposes	Approval (active) 6/4/53
H.R. 4450	Edmondson, Okla.	Ways and Means, H.R.	Increase of allowable medical expense deductions for income tax purposes	Approval (active) in principle, 6/4/53

§ Enacted into Public Law 241, 83rd Congress, Aug. 8, 1953.

† Enacted into Public Law 223, 83rd Congress

PUBLIC RELATIONS CONFERENCE

The following papers were presented before the Sixth Medical Public Relations Conference of the American Medical Association, Nov. 30, 1953, Jefferson Hotel, St. Louis.

Address of Dr. Walter B. Martin, President-Elect, American Medical Association

I am particularly pleased with the theme of this conference because it has an important purpose, public relations. If a business man or some other layman should come into this meeting and glance over the audience, he might wonder what brought us together, why you men, leaders in the medical world, should leave the activities and pleasures of home and travel long distances to meet in conference here today. What important business do you have to transact? What will this profit you and those you look after in your community?

All of you who serve medicine and the medical welfare of your people and who have kept burning the lamp of idealism will often find yourselves puzzled and disturbed by some of the problems of medicine in our modern society. We recall the stature and dignity of the physician that we knew in our youth and the high regard in which he was held by all in his community. Possibly his example inspired us to enter the profession and, by so doing, to strive to render service to humanity. Now, perhaps, we are concerned with the problems in practice that arise in a more complex community and by the attitude of persons toward us, not so much as individuals but as a group. We hear charges and countercharges against our profession. We are aware of conflict between practicing physicians and hospitals and of discussions of problems in the twilight zone between medical practice and preventive medicine. We are conscious of the wide appeal in many areas of proposals to alter the basic set-up of medical practice, by socializing the entire medical profession. These problems cannot be solved by any one of us or by any local or state society acting alone. While their importance or urgency may vary from community to community and from region to region in different degrees, they affect all of us. It is necessary, therefore, that we gather together on a national level and take counsel with each other. Here we should assemble facts, exchange ideas, formulate programs, and, in honesty and sincerity, attempt to perfect a plan of action that will be of help in providing better medical care for all of our people.

I like to think of public relations not as a means of putting ourselves in a better light before the public but as a way by which we can learn better how to serve the public and to constantly enhance the quantity and quality of medical care and its availability. The first step is to look at ourselves as individual practitioners and to examine ourselves as a group, acting through our local, state, and national organizations. Does the light of idealism glow less brightly among us than it did a generation ago? In a crowded, busy life have other considerations than that of service taken first place in our thinking? We have as a professional group a great responsibility. As a learned profession, no other but ourselves can justly judge our competency as physicians or establish standards of our responsibility to our patients and to society. By reason of our expert knowledge in the field of health, we are better able to estimate the effect for good or evil of proposals in the field of health. If our judgment is given honestly and fearlessly for the common good, it should and will carry weight. If it is founded on ignorance or colored by self-interest, it will be disregarded.

It follows, therefore, that the first duty of this group is to consider ways and means of further developing effective relations through state and county organizations with individual physicians. We should strive to stimulate every physician to carry out the major purpose of the American Medical Association, "The advancement of the science and art of medicine and the betterment of public health." This purpose will be accomplished when each member of the profession has due regard for his total obligation as a physician.

I was raised in the country near a small village. There were four men in the community who commanded the respect and the confidence of the community as a whole: the minister, the teacher, the judge, and the doctor, who severally represented in the eyes of the community morality, learning, justice,

and health. These are still fundamental concepts in any community. Somewhere in the growing complexity of life, these concepts may have been lost or confused, but they should be reactivated everywhere. The physician should be as interested in and as responsible for the total health of his community as he was in village life. He should be active in his professional society, in his place of worship, and in his community welfare agencies. He cannot of course "cover the waterfront," but if he selects one or more of these activities, he will be a better doctor, with a broader outlook on life, and its total responsibilities.

One of the primary accomplishments that should flow from this meeting is the stimulation of greater interest in our local society. The impact of the activities of a local society on its community can be greater than that of state or national organizations operating in their broader field. It is unfortunate that the concept of the physician as a man of science has too completely replaced that of the physician as a healer. The pursuit of knowledge has replaced the search for wisdom. Attendance on the hospital staff conferences has depreciated attendance at local society meetings. It is at these society meetings that the real purposes and objectives of organized medicine should be discussed and community health and welfare considered and furthered. Such activities on the part of local societies will solve many of our problems and will meet in their inception many of the criticisms, just and unjust, that are levelled against us.

There is a second field of public relations that concerns us. Medicine has outgrown the little black bag. Health is no longer entirely an individual matter between a physician and a patient, however important that phase of medicine may be. Society has become more complex. The proper field of activity of public health agencies has been extended. Hospitals have expanded and improved and have become a more important factor in community life. Conflicts have arisen between medicine, public health, hospitals, and other agencies in the health field. Development of proper relations between medicine and these other components in the field of health is of extreme importance. Problems that arise need careful joint exploration for the purpose of coordinating all health activities for the total benefit of the public. Here again, the local society should take leadership in its community. On the national level, broad general principles may be laid down and agreed upon, but in a country as large and diverse as ours, these principles must be activated locally and adjusted on the basis of local conditions and needs.

The third phase of public relations is to bring the story of medicine to the people. The scope of the activities of organized medicine of course goes far beyond the department of public relations and covers health education, medical education, protection in the field of food and drugs, plan for extension of medical care, promotion of scientific advancement, and many other endeavors of the American Medical Association. These numerous and valuable activities for the betterment of the public health need to be brought home to all doctors and to all people. The story of the contribution of organized medicine to the public welfare is thrilling and is a record of which we can be justly proud. It needs to be told again and again until it is known in the city streets and at the country crossroads. It needs to be told so that persons know what are the components of good medicine and why socialization of medicine is bad, not for the doctor necessarily but for themselves. Many proposals are being put forward in the field of health, purporting to advance the medical welfare of the people. Some of these are good, some vicious, some silly, and some just plain stupid. It is necessary for us to study these proposals and to consider their effect for good or evil on the public health. It is equally our duty to make public our considered judgment in these matters. It is as much our duty to do this as to explore the cause of a disease in a patient and advise him according to our best knowledge and ability.

Most of the activities of this department can best be carried out on the local level, and correction of abuses can be made effective only there. Our national organization is without punitive power and should have none. Our success in the field of public and professional relations must be accomplished

through the power of persuasion. This should begin in the medical schools, somewhere during the formative years of the undergraduate and graduate student of medicine. The student should learn something of the duty of medicine to society and of the moral obligation that is assumed by a person who is called a physician.

Entrance into a medical society should not be a casual occurrence but should be marked by the seriousness and dignity that accompanies the taking on of a solemn obligation. Perhaps there should be a period of instruction given at intervals by older physicians, covering the ethics of our profession and the physician's duty to the patient, to his community, and to his profession.

You men who are gathered here have an important role to play. If we build well on the foundation of sound and active local societies, if we carry to the people a knowledge of what constitutes good medicine and if we coordinate for the common good all of the forces in the field of health, we need fear no evil.

Address of Dr. Leo H. Bartemeier, Chairman, Committee on Mental Health, American Medical Association

The confidence and the respect that the public manifests toward medicine is neither peculiar to the present era nor solely dependent on the quality of medical care. These favorable attitudes are ancient in their lineage. They are as old as medicine itself. All peoples in all times have placed their faith and their trust in their physicians. The medical man of mediocre ability may be regarded by the community as a far better doctor than a colleague whose intelligence and scientific training are obviously of superior quality.

The judgment of the community is usually correct, because adequate medical care involves the personality of the physician as well as his scientific acumen and his technical skill. His personality and his reputation as a person in the community are of immediate importance to patients and their families. They wish to know about his medical training and his professional experience but "What is he like? What sort of man is he?" are usually their first questions. This interest in the personality of the doctor bears a striking similarity to present-day medical teaching, which maintains that it is as important to know what kind of a person has an illness as it is to know from what kind of illness the patient suffers. Medicine, too, has a strong interest in personality, because perhaps 30 to 40% of illness is known to represent reactions of personality to crises and stress in life situations. In other words, it is not a question whether a patient's illness is organic or functional but rather to what extent is it organic and to what extent is it functional? All sickness is a combination of both in varying proportions.

The majority of sick persons hope that their physician, in addition to his medical knowledge and skill, will have sufficient interest in them so that they may have his complete attention. They want to sense that he cares how they feel and that he will relieve their suffering as quickly as possible. They hope he will be kind and that he will take his time with them. They hope that what they have to tell him will seem as important to him as it does to them.

At the same time, most persons are afraid of doctors when they go to them for the first visit. They are afraid that, in the course of being examined, the doctor will come to know what they know about themselves and that he will criticize them, become angry with them, and dismiss them from his care. They are afraid that the physician will discover that their sickness is more serious than they had suspected. They often fear the worst. At the time of the first consultation, they may show no signs of being afraid. They try to be courageous and to make a good impression, because they hope the doctor will like them. In protecting themselves from expected criticism, they may frequently criticize themselves to ward off any critical attitude on the part of their physician. Others react to their inner fright by boldness or by being critical of the profession or even the doctor himself. Because they are afraid, they attack.

There is another group of patients who consult physicians because of various physical complaints who may be described as repeatedly difficult and disagreeable. Regardless of kindness, patience, and tolerance; regardless of what medicaments

or other treatments are prescribed, this group of patients, instead of obtaining relief from suffering, continue to suffer and frequently complain that they suffer more than before they began treatment. They try to provoke their doctor to become angry with them, to scold them, and to treat them harshly and severely. When they succeed, they seem to improve, but this improvement is only transitory. They tend to be uncooperative in following advice, they misinterpret what their physicians tell them, they break appointments, they are continually dissatisfied, and yet they insist on remaining in their physician's care. Some of these patients then begin to reason that they need surgery, and they are so persuasive and so certain that an operation will relieve them of their abdominal pain or their pelvic symptoms that they sometimes succeed in overcoming their doctor's doubts. For a time, then, they are relieved, but sooner or later their previous symptoms recur, or new symptoms develop. This group of patients, unlike the majority of patients, consult physicians not for relief from pain, discomfort, or distress, but, because they unconsciously seek greater pain and suffering than their original complaints provided. Unlike most persons, this group finds satisfaction in suffering in an effort to relieve their unconscious sense of guilt or to satisfy their masochistic strivings. Every practicing physician is familiar with patients who belong to this group. They often consult one doctor after another. Their motivation toward medicine is in direct contrast to that of most persons.

When persons become sick or are injured in accidents, they simultaneously undergo psychological changes in their relationships to others that are of varying degrees of intensity. These changes, which accompany every sickness or injury, are sometimes more important than the illness itself, and they frequently constitute the primary motivation toward medicine. It is well known to practicing physicians, for example, that many patients who consult them are more frightened than sick and that, when they have been reassured that their illness is not serious and that they will soon recover, their emotional relief makes the importance of their physical complaints shrink to a minimum. They are like children who because of having fallen to the pavement or because of the sight of blood from an abrasion of the skin run screaming to their mothers. They are far more frightened than injured, and, after a moment in their mother's arms and with her reassurance, they quickly resume their play.

Physicians do well to remember that some of their patients who expect their doctors to relieve them by magic-like methods are patients who expect as quick relief as they obtained in their childhood. An infant screaming in its crib becomes instantly silent in the moment it is taken into its mother's arms. Every human being has had identical experiences not only during infancy but also in childhood.

Children undergo many minor and transitory pains and aches as well as slight illnesses that disappear through the care they receive from their mothers. It is, therefore, only natural that they should believe that their mothers understand them very well and know just what to do for them. Many adult patients expect the same understanding and attitude from their physicians, the same omniscience and the same omnipotence they believed their mothers possessed. The past is always a part of the present and often more important than a current illness *per se*. All good clinicians recognize this fact but tend to lose sight of it during a busy practice.

With some patients, the anxiety they suffer in connection with the occurrence of illness is derived from the dread that they may experience the same fate as some member of their family whose death they had secretly wished. Although they are sick and in need of medical care, it is their anxiety that is the more important motivating force in bringing them to the physician. When they say, "You won't let anything happen to me, will you doctor?" they show that they are afraid that they might die. They also show their belief that only their doctor can save them. To admonish such a patient not to "be so foolish" or to become angry because one has told the patient again and again that he will recover shows that one does not understand the patient who has the illness. Repeated failure to understand patients in matters of a serious nature to them tends to motivate them away from medicine.

In the course of sickness that is incapacitating, many persons undergo a psychological regression. The feeling of being helpless and of having to be completely dependent upon others even, perhaps, to the extent of having to be fed, bathed, and toileted, is a reinstatement to the period of infancy. In these circumstances, some patients make incessant demands on their physicians, their nurses, and their families. They become afraid to be left alone, burst into tears over slight disappointments, and are unable to show any consideration whatever for their physicians or anyone else. The psychological change that has taken place in such patients consists in the fact that their psychic energy, which was formerly invested in their families and friends, their work, and their play, has become reinvested entirely upon themselves. This regression to an early phase of emotional life, which may occur, for example, in a patient with a fractured femur, is not "an act" or an intentional way of behaving. It is, on the contrary, a reaction of the personality in connection with the treatment of a fractured femur. It becomes the more important aspect of the illness. The patient's family knows that whenever he must be confined to bed he becomes very difficult to care for, that, under these circumstances, he is "not like his usual self" and that he is not intentionally dramatic. To become severe with such a patient, to restrict the frequent attention he needs, and to prevent him from having visitors is to do both the patient and his family a serious disservice. It demonstrates that the physician does not understand the patient, and it comes as no surprise when his services are discontinued by the family. Clinicians who do understand the concomitant psychological alterations in such patients are less likely to lose their tempers with them. To remain calm and collected in situations in which both the patient and the members of the family are anxious and distraught has a quieting and reassuring effect and has always been characteristic of the good physician. The following statements in the report of the first Conference on Psychiatry and Medical Education are pertinent:

"The medical profession has in our society gained a very large measure of respect and trust. People turn to physicians for salvation from distress or anxiety of the most varied origins. Such a challenge to the medical profession cannot be ignored. In what measure can it be met? The traditional and continuing major function of the physician is to care for patients with physical illness. The current demand is that he perform this function with sufficient understanding of the emotional attitudes and social problems of the patient and those in close relationship to him, so that the patient and the family are enabled to participate in and make optimal use of medical care. This demand is a realistic one which the physician can be expected to fill.

"Advances in medical science have brought about the realization that mental and emotional conditions cause or contribute to illness (with either physical or psychological symptomatology) and affect the course of treatment. As a result, the physician is becoming more aware of the concept of multiple causality or a constellation of causal factors in the diagnosis and treatment of pathology.

"The physician's functions overlap to a considerable extent the functions of other professional workers in the community. The medical profession must avoid the mistake of thinking that it can do the whole job. Such mistaken ideas are fostered by narrow professional jealousies and by the public itself, as is indicated in the wide range and varied types of needs which the doctor is expected to serve. Medicine has provided such excellent service in certain fields of somatic disease that the assumption is naturally made that it can be similarly competent in other areas. This has brought about the attitude of looking to the physician for the solution of a good many problems, some of which are or should be within his province, and some of which are not. What then, is the special contribution of the physician? It is true that no one doctor can master all the technical knowledge and skills of the different specialties—science has grown so fast. But it is not asking a doctor to take on the specialty of psychiatry to ask him to use some general principles which psychiatry (and physiology) can place in his hands. It is not suggested that a doctor abandon his valuable laboratory reports, but it is urged that he keep them from pushing other considerations

out of the picture. There are two sentences of Francis Peabody, a professor of medicine, which describe the doctor's full job. 'The clinical picture is not just a photograph of a man sick in bed: it is an impressionistic painting of the patient surrounded by his home, his work, his relations, his friends, his joys, sorrows, hopes and fears.' 'The secret of the care of the patient is in caring for the patient.' The good doctor will balance the physiological data in his field against the condition of the patient as a person in his family and social background; he will try to increase the patient's security in an insecure world; to increase the patient's dignity as an individual and not a case, and to make him feel it is important to him, the physician, that this particular patient should return to his place in the world. As a result of these unique qualities and contributions, the physician stands in the community as a special authority to whom one can go with trust and confidence."

This was the consensus of some 70-odd professors of psychiatry and deans of medical schools in a conference in 1951. In preparation for this conference, 3,500 questionnaires were sent to bankers, industrialists, unions, teachers, lawyers, ministers, social scientists, and over 400 women, the larger proportion being housewives. Over 700 replies were received. The questionnaires consisted of 10 questions asking what persons in the community think are the common emotional needs of people, how the doctor could best meet these needs, and whether he is doing so. The replies emphasized repeatedly that doctors are viewed as hardworking, conscientious, and respected; that too much is expected of doctors; that doctors have an olympian view of themselves; that doctors are too busy to do all they might; that in the treatment of physical disease, doctors do not consider the feelings of patients and even accentuate anxieties; that they increase fear by not explaining things to patients in nontechnical language and that there is a great tendency to turn to a nonmedical, miscellaneous assortment of persons for outside help. In reply to the question, "Can the doctor help with emotional needs?" most answers indicated that (1) the doctor could help in terms of counseling, being a good listener, showing continued sympathy and understanding of the patient as a human being and eliminating assembly-line methods. The replies to the question, "What are the common emotional needs of people?" included a wide range: health and economic security, feelings of loneliness, insecurity, anxiety, frustration, familial needs, and fears of many kinds. These are the motivations that influence a considerable percentage of the public toward medicine. In some instances, persons turn to their physicians openly for advice and assistance with personal and family problems because it is their physicians in whom they have the greatest faith and confidence. In a good many other instances, their worries, fears, and feelings of helplessness over their situations are concealed beneath their presenting complaints of headaches, nervousness, tenseness, backache, mild anorexia, and undue fatigue. More and more persons are turning to doctors with problems that physicians can regard only as being beyond the scope of their professional training, and it is only natural that doctors develop the feeling that these patients are unrealistic in their requests. To refer these patients to another physician, to a clergyman, or to anyone else invariably makes the patient feel unwanted, unreasonable, and rejected. It is far better to do what one can, to recognize that these personal emotional crises are affecting the health of patients, that they are medical problems, and that they belong to the province of medicine. Finally, there is urgent need for recognition of the fact that all patients who are motivated to medicine by their anxiety are as children who turn very naturally to their physicians, whom they endow with the same wisdom and good judgment that they always thought that their mother or father possessed.

Address of Dr. Edwin Crosby, Director, Joint Commission on Accreditation of Hospitals

The program of the Joint Commission on Accreditation of Hospitals is a truly fine device for assuring the public of good medical care, and, in my judgment, definitely a positive public relations asset. There is without doubt considerable lack of understanding of the Joint Commission at the national level,

especially how it operates through its board of commissioners, and I should like to review for you who it is that are on this board of commissioners. First of all, there are three physicians from the American College of Physicians, three surgeons from the American College of Surgeons, six representatives from the American Medical Association, including three from your own Board of Trustees, seven representatives of the American Hospital Association, three of whom are physicians, and one representative from the Canadian Medical Association. Thus, of 20 members of the board of commissioners of the Joint Commission, all but 4 are physicians and most are practicing medicine either in the United States or in Canada.

These men are dedicated to the purpose of the Joint Commission, and they do all that they can within their power to carry out this purpose. I should like to read to you now from the bylaws of the Joint Commission as to what the purpose of this Joint Commission is. It is "to conduct an inspection and accreditation program that will encourage physicians and hospitals of the United States and Canada voluntarily (1) to apply certain basic principles of organization and administration for efficient care of the patient; (2) to promote high quality of medical and hospital care in all its aspects in order to give patients the greatest benefits that medical science has to offer; and (3) to maintain the essential diagnostic and therapeutic services in the hospital through coordinated effort of the organized medical staff and the governing board of the hospital."

It is tremendously important that this purpose reach the grass roots of our country, that it reach the grass roots with the same story that we know at the national level. There is, to say the least, some confusion at the grass roots about the purposes of the Joint Commission. We have been called various things, including the "medical Pentagon in Chicago." And there is a definite misunderstanding, as evidenced by some of the letters we receive, about what we are doing for the benefit of patients, because we have been called "an aspect of medical socialism."

Your job, it seems to me, is to explain that the Joint Commission is one of the greatest bulwarks against socialism that medicine and the hospital professions have ever constructed. It assures the public that our primary concern is for the patient and the care he receives. As positive evidence of this, doctors in hospitals in this country are spending almost one half million dollars each year of their own funds to support this program voluntarily, so that the quality of medical care in hospitals can be raised on a voluntary and not a compulsory basis.

I would like to show you how I think you might tackle this at the local level, because I think that is where we need to tackle this problem. Let me give you just a brief case report of a recent request we received in our offices in Chicago, where there was evidence that there was no understanding at the local level.

An inquiry came from one of the wire services in Chicago that had originated in one of their offices in the South. The reporter asked me three questions: First of all, "What is this Joint Commission on Accreditation of Hospitals? I have never heard of it." Two, "Is the Joint Commission really going to disapprove 500 hospitals in 1953?" Three, "Are the standards of the Joint Commission tougher than the ones the American College of Surgeons has used for 35 years?" Let me answer the last two questions first. I was pleased to tell him that the records showed that we had upgraded from no accreditation twice as many hospitals as we had downgraded. Furthermore, the records showed so far for this year that there was a net increase of the number of hospitals in the United States and Canada that carried accreditation under the aegis of the Joint Commission. As far as the standards are concerned, they are the same standards that the College of Surgeons had, because we took them over lock, stock, and barrel, and there have only been two changes made in these standards to improve them.

"Well, this is a very fundamental thing," he said, "and I would like to write a story about it. How shall I write a positive story about the Joint Commission?" He went on to say, "I was a patient once in a hospital, and, as a patient with a pain in my stomach, my doctor sent me to the hospital. What can I expect in an accredited hospital that I wouldn't get maybe in a nonaccredited hospital?" I was amazed at the number of things which I was able to tell him that he might expect in an accredited hospital that he might not expect in a nonaccredited

hospital. Here they are: First of all, the medical staff is made up of qualified physicians, graduates of approved schools of medicine in the United States. These physicians are practicing medicine and surgery in the areas to which they are qualified by experience and training. Second, before you are operated on, you will have a history, a physical examination, the necessary laboratory work done, and a preoperative diagnosis made by your surgeon. If he feels that a consultation is necessary, he will call in a consultant. All of this, of course, unless there is a real emergency for you to be operated on immediately. Thirdly, when you go to the operating room, you know that you will be operated on by a qualified surgeon, as determined by the local medical staff. He will be assisted by a medical assistant, and you will be surrounded by all the necessary technical controls to assure you of sterilization of supplies.

After operation, you will be followed by the anesthesiologist in a recovery room, if the hospital is large enough. After that, you will be assisted by medicine's indispensable man, the pathologist. He will receive the tissue that was removed at operation, will examine it, and will make a report on it that will be included in your medical record. Then all of the patient's care in that hospital will be reviewed by the medical staff at least once a month by the various committees. The medical staff evaluates itself and governs itself subject to the ultimate authority of the board of trustees. In addition to this, there are many other things you might expect in an accredited hospital. You will find that there are nurses. In some hospitals, there are no nurses. You will find that there are qualified technicians, that you are being taken care of in a modern plant. If it is not modern, you will be assured that there are all the precautions that are necessary to be taken to prevent fire. The reporter's answer to me was this, "All this and heaven too?" I said, "Yes, that is what you can expect in an accredited hospital."

This is something that I am proud of. I think that every doctor in the United States and Canada can and should be just as proud as I of the accreditation program. It is important to tell this story. The medical profession is working with the hospitals of this country. They are paying from their own pockets, from their own funds, to assure the public that they will receive the best quality of medical care available. All hospitals, large and small, with accreditation have the stamp of a third party that the standards of adequate medical care have been met.

Let me quote from something the charter chairman of our commission once said. Dr. Gunnar Gundersen, an A. M. A. Trustee, in talking of the Joint Commission, said: "It is a voluntary movement, representing the best thinking and the best inspiration of five of the most powerful groups in the world dealing with health. As our duties [those of the board of the commissioners] are discharged well, the benefits to mankind through our profession, through our hospitals, and for our civilization are on record." This is from the national level.

Address of Dr. Durward Blakey, Secretary-Treasurer, Clarksdale and Six Counties Medical Society, Clarksdale, Miss.

When we say that a program works, we must have firmly in mind what the system is and what it is expected to do. In the instance before us today, we are concerned with the public relations value of a working audit system, and, most assuredly, our audit system could not be working unless it did produce bountiful results in the field of public relations. In a sense, public relations and an audit system are inseparable.

It is impossible to separate completely the activities of a hospital and be able to say, for example, that the management is poor but the public relations department is excellent. The multitude of operations contributing to the success of the hospital all exert their effects, one upon the other, to produce a composite whole. In this respect, public relations must be considered and actually is an attitude.

There is one attitude in every hospital, and it is reflected by the employees, the management, the medical staff, and the auxiliary. This attitude is rapidly communicated to the new patient as well as to the entire community, and it is this attitude that constitutes our most important public relations asset. Therefore, when we say that our audit system works, we are, in fact, saying that the doctors of our community have ac-

cepted a leading role and assumed the responsibility, which can only be theirs, of proving to the employees, management, auxiliary, and public that the best possible medical care is guaranteed to the patient. These persons cannot be fooled. They are satisfied in their own minds whether this situation actually exists or is merely said to exist. If they are convinced it exists, their good opinions come back to you many times from their friends, neighbors, and acquaintances. This person-to-person communication is our most important field of public relations.

It is impossible to assume that good management can offset a poor or absent medical policy. There is no means whereby a hospital can render the best possible medical care unless the medical staff has adopted and strictly enforced a plan whereby every doctor's ability is constantly checked and his privileges assigned accordingly. A medical audit system represents an ideal. The success of any venture depends on the effort expended in its behalf by its proponents. We must always be sure that the idea or service we have to sell is what the public wants. At the same time, it is important to know that the majority of those involved in the venture are sincere in voting for it rather than paying lip service merely because they are afraid to be on record as opposed to it.

When our doctors first met to draw up the bylaws, rules, and regulations of our hospital, it was evident that the mass of work involved did not appeal to anyone. There was no more than the usual incentive every doctor has to be a part of something better than we have had before. There may have been a feeling that whatever was drawn would be loosely enforced, and this might well have been the case. Patients in our area have long been able to keep their own medical counsel, being, as they are, in close proximity to a leading medical center. Referral of patients for consultation locally was about as low as it could be, thus contributing to an increase in cost to the patient, since they did have to leave town for consultations. Such a condition over a period of time could only result in lowering public confidence in the profession.

Under our new bylaws, it was evident from the beginning that consultations were the one means of keeping the audit committee satisfied. Many meetings were devoted to drawing rules covering required consultations. Gynecologic surgery without consultation was eliminated. Writing consultations whether required or not has become almost routine. An early high cesarean section rate was fully audited and, though shown to be justified, served full notice that the staff would live by its bylaws. The pathologist was called into conference with the tissue committee and invited to give strict interpretations of all tissues submitted to him.

By now, it had become obvious that our doctors were responding to the incentive offered by a system of which they were a part and that they approved a searching scrutiny of their work by their colleagues. If there were any who did not fully approve, they would have found it necessary to comply because of the pressure characteristics of the audit system. We felt justified, therefore, in releasing some public information to the press on our system.

It had been rumored for some time that a patient could hardly be mistreated in the new hospital, but after the first major feature written in our local paper, the profession as well as the hospital not only gained a wealth of favorable comment but obviously assumed a place and a stature in the eyes of the community.

It is well to pause at this point to reaffirm what has already been indicated. Public relations and publicity are not the same, though good publicity adds a great deal to the public's opinion of the hospital, thus enhancing the public relations. Feature articles in the press and over the radio are extremely important in crystallizing public opinion, but, no matter what is doled out to the reporters, it is practically valueless unless it is borne out by the actions of all those concerned in the operation of the hospital.

Public Relations, as we are prone to think of it, is something tangible. We should forget this idea. In its simplest sense, public relations is nothing more than the enthusiastic devotion to duty of all those concerned in the operation of the hospital, coupled with a sense of something worth while being accomplished and a feeling of oneness or *esprit-de-corps* between all those persons actively working together. This feeling can be

generated by the medical staff as by no other group in the institution. The effect of firm medical staff government on the nursing and maintenance personnel is of the utmost importance and of incalculable benefit. The institution is the place where the doctors work. If they are slipshod in managing themselves, it will inevitably be reflected by less than the best possible in patient care and, therefore, in poor public relations.

There are many opportunities for good public relations growing out of staff government. The crux of good staff government is the audit system. The active audit of the records, the review of patients in the hospital, analysis of tissue reports, operative indices, morbidity, mortality, etc., are of no value unless everyone realizes that a strict accounting of derelictions will be had. There is considerable overlapping in the work of the various committees and service reports necessary to proper functioning of the audit system. This double check almost completely eliminates the chance of internal politics, which is of prime importance.

After the publication of our first feature on staff government, it soon became obvious to the officers of the staff that at least the vast majority of the doctors favored interpretation of the bylaws, rules, and regulations in the strictest sense. A new feature dealing entirely with the audit system was prepared by a reporter invited for the purpose. This article aroused a flood of favorable comment, not only at home but throughout the state. It is primarily because of this article that this paper is being presented here today. Though it might appear that the development of our public relations program was planned, this is not the case. We have tried to develop a good public relations program, but what we have done has been a natural outgrowth of the audit program.

We should never forget our controlling body. The success or failure of any hospital depends on its medical staff, but a good sound policy in staff government can quickly elicit the solid support of the Trustees. These persons are forgotten all too often, but they never forget us. Good liaison pays untold dividends. There are many other groups intimately concerned with the functioning of the hospital though not primarily a part of it. These include, among others, our volunteer health agencies, official health agencies, newspaper and radio personnel, ministers and church groups, and civic clubs. Representatives of these groups can find the pulse of the hospital very quickly and are attuned to the attitude of the operating personnel. The hospital auxiliary will feel the effects of medical policy in morale of the hospital. If the auxiliary does not pick it up, you may be sure there is little to pick up.

It is not enough to give good medical care—the patient must be told he is getting it and the fact proved. For example, there will seldom, if ever, be a complaint from a patient for the charge of a routine admission roentgenogram if he is given a small folder outlining the reasons for the procedure. Small brochures on the purpose and scope of the hospital given to the patient are well worth while.

Morale, it has been said, is a lot of little things. In hospital work, one of these can be an active audit program. If it is effective, the medical care system will be effective, and the doctors' morale will be reflected by the hospital personnel and the auxiliary. Call it what you will, morale or *esprit-de-corps*, the result is good patient care. When this state of affairs is reached, the hospital acquires the human element that is the ultimate in good public relations.

At the time of this writing and, growing out of our staff government, we have evolved a community blood bank, poliomyelitis center, doctor locator service, emergency call system, and grievance committee. In addition, we have begun a memorial medical library. The opportunities offered for publicity and enhanced public opinion are evident. Our doctors are taking the problem of individual public relations back to their offices, to the civic clubs, and to their routine lives as citizens of the community. The far-reaching effects of the audit system pay ever-increasing dividends.

Our hospital has 100 beds and was built under the Hill-Burton plan. It is not the only hospital in the community. At this writing, it has been open and receiving patients only 11 months. It would seem impossible that so much could be accomplished in such a short period, yet it has. While comparable hospitals in the mid-South have had about 30% occupancy

during the first year, ours has had nearly 38% so far, and, on the present basis, it will be higher when the year has ended. We feel this margin of occupancy is due in its entirety to our public relations program and that it cannot fail to increase as time goes on. We know we are on the right track. We know we have what the public wants and is entitled to receive—the best medical care possible. We know the public is learning this fact and growing to appreciate it. We know that we have worked long and hard over our program of staff government. We know we are better doctors because of it, and we know the patient is the sole beneficiary.

When our chief of staff was elected, in his acceptance, he stated that his policy would always be "equal rights to all—special privileges to none." He has repeated it on every possible occasion. In our hospital, it has come to mean good medical care—the best available—to everyone. We have come far but the limit is not in sight.

In summary, the public relations values of an audit system may be divided into three parts, one of which we can assign to the public, one to the physicians of the staff, and one to the hospital itself.

To the public, the audit system (1) builds confidence and trust in the doctors and the hospital, and (2) assures the patient of treatment which is completely competent on the highest ethical plane. To the hospital, the audit system (1) assures competent and complete medical records; (2) finds and points the way to correction of administrative deficiencies; (3) materially advances the hospital's efforts toward accreditation; and (4) fosters close liaison and promotes understanding between the medical staff and the trustees. To the physician, the audit system (1) is the best argument and the best reason for exclusion of external control of the practice of medicine; (2) means that privileges are assigned solely on the basis of professional ability and ethical practices; (3) promotes competent practice from two standpoints: *a.* incentive, *b.* pressure; and (4) eliminates, insofar as possible, both internal and external politics on the staff and, coupled with a capable and conscientious chief of staff, assures impartiality and fairness to all members.

Address of Dr. David W. McCarty, Chairman of the Board of Supervisors of the Colorado State Medical Society

I represent before this meeting a type of state board organized for self-discipline which was pioneered by the Colorado Medical Society, which has been highly successful during the six years of its existence, and of which the society is justly proud. The chairman has asked that my part in this panel be to describe to you, not so much the mechanics of a state grievance committee but the realistic operation of such a committee, set up to perform definite services and having been given the authority by which those services can be accomplished. To describe the action of such a committee is like trying to tell a medical student what psychotherapy is; it simply cannot be done adequately without being able to demonstrate the board in session.

Departing for a moment from the realistic approach, it seems to me necessary that we first establish the position of the state grievance committee. In the first place it should not be labeled a "grievance committee," because, from the start, it should have duties beyond those of simply investigating complaints. It should be empowered to initiate its own investigations concerning professional conduct. It should be able to prosecute serious offenses before a judicial body. From the hearing of complaints, their investigation, and their prosecution, the board becomes a repository of a great deal of information that would be lost if it were not to carry on an educational program in proper professional conduct, in better patient-doctor and doctor-doctor relationships, and, finally, in formulating good public relations for the medical profession.

In setting up a committee on professional conduct, it seems to me that at least four conditions should be fulfilled. It should have: 1. The approval and respect of the members of the state society and the confidence of the public. 2. To function honestly and impartially, it should be an elective body—certainly not honorary—elected by the house of delegates on nomination of the component societies. In our set-up, the board is elected by the house of delegates, but the nominations are made from the component societies with a geographical dis-

tribution. There are 12 areas, 6 of which would nominate a member of the board each year. 3. Then the meetings must be held in such a manner that there is no breach of confidence. 4. It should be provided the authority necessary to carry out complete investigations. If the board is to have authority necessary to carry out complete investigations, it must have the power to compel the attendance of the members of the society in order that they can inform the board. It can only invite non-members, but the members of the society who refuse to appear can be cited for contempt before our board of councilors.

The Colorado board of supervisors has no power to try a member, and it has no power to impose discipline. It is set up as a division of the judiciary department and can prosecute charges before the board of councilors, which has the disciplinary power, the board of medical examiners, or a criminal court.

Unless the board has publicity, new members entering the state society each year will be unaware of its functions, and older members will become forgetful of its functions. It is important to keep both of these groups informed, and the laity also must be informed of the existence of such a board. Our board averages around 55 cases per year. I say "cases" instead of complaints, because some are from information and are not complaints. The only way that I know that I could present a realistic picture of the operation of our board is to try to give you some hypothetical cases embodying some of the frequently occurring or disturbing problems, with you as the grand jury.

Complaints reach the board via a number of routes, namely, over the telephone to the secretary of the society, by letter from patients, from other agencies, attorneys, the Blue Shield, the A. M. A. Over-charging still comprises about 50% of the complaints received by our board. It formerly was 70%, and we are glad that it has remained at 50% for the last three or four years.

Here is a typical case: The patient went to a doctor with what he felt to be a minor complaint. He was given an examination. He had subsequent treatment, after which he received a bill for \$50. The patient felt the bill was too high. He said the treatment did no good anyway. He did not pay his bill. He has never discussed it with the doctor. Now the bill is being turned over to a collection agency.

Our procedure is somewhat like this: A letter is sent to the complainant stating that an investigation is under way, frequently mentioning the fact that we meet only once a month and it may be some time before he has a complete report. If indicated, the complainant is advised to appear in person before the board. Then a letter goes to the doctor stating the nature of the complaint and requesting information regarding the case. If it is felt necessary, he is asked to appear before the next meeting of the board. In a case such as I have just described, a request is made for an itemized bill. We frequently ask the doctor in the letter if he wishes to call in the patient and attempt to make some amicable adjustment himself. Frequently, our letter to the doctor is his first information that there has been a complaint registered against him. If the bill is already in the hands of the collector, we have sometimes been successful in asking the doctor to request delaying action pending our investigation. Sometimes, we have asked the collector ourselves if he would delay the action.

Now, what can be learned from a case like this? In the first place, the itemized bill from the doctor may show the fee to have been entirely commensurate with services rendered, the type of treatment, and the type of studies. If the doctor had rendered an itemized bill in the first place, or had taken three minutes to explain the need for certain examinations and the cost of the medication and treatment, the complaint would never have arisen. In such a case, the patient is so advised and told that his bill should be paid.

Another possibility is that the patient is a "deadbeat." He has made no attempt to pay the bill. He has made no attempt to discuss it with the doctor. He may be complaining now only because legal steps are taken to collect it. When the patient complains that the treatment did no good anyway, it is the feeling of our board that the doctor would do well to become his own public relations officer and reconsider his fee in view of the results obtained. Recently, we have had two complaints

of patients who have employed an obstetrician and, as sometimes happens, the baby was born before the arrival of the obstetrician. We took this matter up with our state society of obstetricians, and they maintain that, when they accept a case, if the birth is precipitate and they are unable to get there in time, they still have assumed full responsibility of the case and they are, therefore, justified in collecting their full fee. The patients do not agree.

We feel that the most serious charge that reaches our board is that of neglect of a patient. Here is a typical case: A pathetic widow appears before the board. Her husband was a retired school teacher who had been able to do some substitution work. The family doctor had become concerned about his condition sufficiently that he had asked an internist to hospitalize the man for study because he felt it could not be done on an outpatient basis. The patient went to the hospital at 3 p. m. He had not yet been seen by the doctor at 7:30, and his wife called the physician's home. The doctor examined the patient at about 8 p. m., felt that his condition was not serious, and so informed the wife. The patient had a bad night and was not seen the next morning. In the middle of the afternoon, it was necessary for the house physician to attend the patient. By evening, it was necessary to call in a urologist for catheterization, which was difficult and required an anesthetic. The wife then talked to the physician in charge, and the patient seemed to be doing all right, but, by 1 o'clock in the morning, he had convulsions, and he was dead at the time the physician arrived at the hospital.

Now, on the surface, this would sound like a serious complaint, and it certainly sounds as if there were neglect of the patient involved, so the physician was asked to appear before the board. His story was considerably different from that of the widow. The nurse had informed him at his office of the arrival of the patient at the hospital, stating that his condition seemed good. His usual practice was to go to the hospital before dinner, but in this case he had his dinner and then went to the hospital. He checked the man and felt his condition was relatively good, but, on his arrival at the hospital the next morning, he found that the man had considerably more severe congestive failure than he had realized, and he discussed it with the house physician and started administration of a mercurial diuretic, telling the house physician that he might run into trouble because of urinary difficulties. The house physician was able to catheterize the man after his diuresis started with considerable difficulty, and by evening it was necessary for a urologist to see the man. He required an anesthetic for the insertion of a retention catheter. The patient responded, but at 1:30 went into convulsions and died within 10 minutes.

Certainly in such a case, there is no evidence of gross neglect of the patient. The wife was not aware of a good many of the doctor's visits to her husband. We do think, however, that the doctor made some mistakes. He certainly should have seen the patient before six hours had elapsed. He made a common mistake of telling the family that the patient's condition was good. In this case, the widow had gone over the course of events with her son and with her attorney because it was felt that her husband was in relatively good condition, and yet in 36 hours he was dead.

Someone has asked me how much should be included in a letter that states the final action of a mediation committee. In a case like this, a letter to the widow will state that we had investigated the case, the hospital records were checked, and witnesses were questioned, and it was the feeling of the board that there was no neglect, that her husband had received adequate medical treatment. In a case like this, certainly more detailed information will have to go either to the son or to the attorney.

One of our problems at present, and certainly a problem that would concern a meeting of this type, is that of individual publicity that smacks of advertising. The Code of Medical Ethics states that solicitation of patients, either directly or indirectly, is not ethical. Colleagues are particularly critical when the name of some doctor appears too frequently in the press, and the distinction between what is ethical and what is not ethical becomes very fine.

Here is a case of a clinic that made an announcement in the papers of its opening. The group actually consisted of 4 full-time members, 3 part-time doctors, but the announcement also listed 14 of the leading consulting specialists who had agreed to see patients referred by the clinic, but in their own offices and rendering their own bills.

The newspapers felt that the opening of the clinic was newsworthy. They called it a business-type article, and they played it up to a three-column spread with pictures, and they captioned it, "Mayo Type Clinic Is Opened." The board investigation revealed that the information had been requested by the papers and it had been gladly given and in much detail by the clinic. The idea of the publicity had not been cleared with any public relations committee, and the information furnished by the doctors was not in good taste and was not entirely truthful.

A case similar to the one I have cited appeared before the Colorado State Medical Society's Board of Supervisors and required four months of investigation and the testimony of 36 witnesses. It required the filing of charges with the board of councilors and ended with the successful prosecution of the charges before that board.

I have cited this last type of case for two reasons. I feel that it shows that our board of supervisors is a mediation committee with teeth, and this type of case concerned with personal publicity that smacks of solicitation of patients has so many ramifications that it should be a good one to discuss at a meeting such as this devoted to public relations.

Address of Dr. Henry V. Weinert, Chairman, Tissue Committee, St. Mary's Hospital, Passaic, N. J.

To orient and evaluate the population and bed capacities of the geographical areas that the members of this conference reside in with ours, I would like to specify that there are available in Passaic, N. J., three hospitals: St. Mary's with 192 beds, the Passaic General with 234 beds, and the Beth Israel with 60 beds, all combined, serving an area with a population of 275,000.

In 1946, St. Mary's Hospital was assigned a new Administrator, Sister Eileen Teresa. After completing her studies in nursing, she served as an assistant to the previous administrator. In these capacities, she came into direct contact with patients and public, and thus a fund of information and facts concerning existing surgical practices was made available to her. It was, therefore, not difficult for her to evaluate situations and to differentiate proper from improper practices.

Correction of irregularities was decided on and instituted. After lesser improprieties were corrected, the major blemishes of the profession, which were then just beginning to receive unfavorable publicity, were attacked. Among these were the practices of fee splitting, ghost surgery, and unnecessary surgery. Sister Eileen decided that this institution would not be a workshop for physicians who did not respect the dignity of the hospital or consider the economic and personal inconveniences of the public when indulging in these abuses. The lack of a hospital in which to perform surgery on poorly workedup cases, or patients with questionable need for surgery will of necessity eliminate most of these unethical practices.

Fee splitting was managed by insistence on the method devised and recommended by the College of Surgeons. Any additional safeguard in the control of this very difficult problem, we felt, would be helpful. All physicians were therefore graded so that there could not be no doubt as to which operative procedures they were capable of performing or merely assisting in. The recording of the surgeon and assistants on the operative record, according to their grading by the administration, thus forms the basis on which billing for services according to the College of Surgeons rules are made.

The remaining two evils, ghost surgery and unnecessary surgery, required the setting up of legislation, i. e., rules, inspection, and enforcement, as is familiarly done to combat irregularities. A strict set of rules was formulated. Any hospital planning a tissue committee should first formulate this legislation as a basic necessity. Without surgical control rules, the tissue committee could only review cases of absent or minimal

pathology which would, indeed, be a poor surgical audit and certainly would not prevent ghost or unnecessary surgery. The tissue committee then becomes the inspection or policing agency, and its findings can be transmitted to properly designated authority for correction of irregularities.

The rules so adopted required, among other details, compulsory preoperative consultation in such procedures as dilatation and curettage, hysterectomy, uterine suspensions, lysis of adhesions, herniation of intervertebral disks, and all procedures specified in the Catholic Code of Ethics. The rules further made it mandatory that the physician, to be recorded as the operating surgeon in the case, personally interview and examine the patient and prescribe treatment personally. Strict adherence to these rules and verification by the Administration that they are fulfilled must lead to a complete eradication of ghost surgery.

Having completed our rules program, we embarked on the method of inspection, that is, auditing. A communication addressed to Dr. Malcolm MacEachern requesting information on this problem brought the following response, dated April 25, 1949: "The American College of Surgeons does not have a bulletin on the subject, although we hope to have one in the near future. The whole idea and plan of a tissue committee is fairly new."

The committee proceeded to devise its own plan. It goes far beyond the review of cases in which the pathologist simply records the removal of normal or minimal pathological areas. It includes also a review of all appendectomies, all reproductive organ surgery, all emergencies, all cases in which definitive surgery was not accomplished, all cases in which there is a marked disparity between preoperative and postoperative diagnosis. By this method, no questionable or unnecessary surgery can escape review and audit, and the compulsion of correction by the erring physician must lead to the abolition of unnecessary surgery.

In November, 1949, the committee held its first audit. Monthly audits have been held since. The information obtained was so instructive and illuminating that I was urged to publish the facts. This was done, and on Nov. 8, 1952, THE JOURNAL published the article entitled "Effectiveness of Hospital Tissue Committee in Raising Surgical Standards," which outlines in detail the procedure to be followed in organizing such a committee. We are reviewing in detail and auditing approximately 1,400 charts yearly.

Prior to committee audit, we found appendectomies averaged 28% of the total surgical cases, of which 20% were found to have minimal or no pathology. This has been reduced, and now appendectomies average 8 to 9% of the total surgery, with 5% of these receiving adverse audit. Most spectacular results were obtained in the category of emergency surgery. Early in our study, we found 29% of emergency surgery lacked pathology or need of surgery. This rapidly fell to 10%, and this year in emergency surgery, averaging 40 cases a month, it is most unusual to find months in which more than one or two cases are recorded unfavorably, which averages 3 to 5%. No longer do we hear in the hospital the complaints and display of anger of the conscientious physician who, while observing a case carefully, or not recommending surgery, found emergency surgery was performed with the removal of a normal organ.

Because of strict consultation demands, procedures such as uterine suspension, lysis of adhesions, and hysterectomies for functional bleeding with no pathology have become a rarity. The greatest improvement occurred after the first summons of physicians for review and censure. To fail to review and insist on improvement from those found derelict would mean that the tissue committee would only amass a great deal of useless paper work.

Good public relations for the medical profession begins and ends with the individual physician. The topic of illness, which eventually involves the physician and, often the hospital, is, without doubt, high on the agenda of family and friendly gatherings. It is not surprising, then, that isolated irregularities and distrusts multiply rapidly, leading to a lessening of respect and trust of the entire profession. It is, therefore, regretful that I must report that we did not obtain the cooperation of the physicians at the outset in this most essential project

for bettering public relations. We persisted in our labors and submitted unbiased, truthful reports, instead of white-washed opinions that discouragement could well have initiated. Our forte was complete cooperation of the governing board, without which it is useless to function.

Gradually, the attitude of the physicians improved. We were aided by many factors. The publication of the article brought congratulatory and complimentary replies from nationally prominent physicians, welfare workers, educational institutions, and hospitals. To remove the awe of secrecy and questionable righteousness of the committee, we instituted a program in which two noncommittee member physicians are permitted to sit in at deliberations, at their own request, as guest observers. These observers are our greatest boosters. The director of surgery and president of the medical staff are invited to each meeting.

The announcement to the staff that the Joint Commission on Accreditation of Hospitals will require professional auditing for accreditation broke the final barrier of resistance. Today, we have excellent cooperation by the physicians, with an evident atmosphere of a desire to maintain individual acceptable audit status. So we can conclude that, properly encouraged, physicians will permit self-examination and correction, which is excellent prophylactic therapy for future adverse publicity and another step to good public relations.

THE PHYSICIAN'S FEDERAL INCOME TAX

Federal income taxpayers on a calendar year basis must on or before March 15 do two things: 1. They must file their final returns for the year 1953. 2. They must file a declaration of estimated tax for 1954.

Copies of appropriate forms have already been distributed to prior taxpayers, together with a small booklet which presents the general requirements of the law. Physicians who are for the first time subject to the requirements of the federal income tax law may obtain the necessary forms from the office of the Director of Internal Revenue having jurisdiction.

GROSS INCOME

A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, assuming that the return is on a cash receipts and disbursements basis, plus such money as he has received from investments and from other sources.

If a physician receives a salary as compensation for services rendered and in addition thereto living quarters or meals, the value to the physician of the quarters and meals so furnished ordinarily constitutes income subject to tax. If, however, living quarters or meals are furnished for the convenience of the employer, the value thereof need not be computed and added to the compensation otherwise received by the physician unless such quarters and meals are furnished as a part of compensation.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. As far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed:

Office Rent.—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a

physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance.—Expenditures for office maintenance, as for heating, lighting, telephone service, and the services of attendants, are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs, and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture, and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment.—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment such as has been described, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical, and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment, and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation deductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal, or average rates of depreciation, the following percentages have been suggested: automobiles, 25% a year; ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments, and diagnostic apparatus, 10% a year; office furniture, 5% a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the average value of the article at the end of its useful life, shall not be greater than its purchase price. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in each case.

Dues.—Dues paid to societies of strictly professional nature are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are generally held to constitute personal expenses and as such are not deductible. If, however, membership in social organizations, such as a country club, is maintained both for personal and professional or business purposes and if evidence can be produced to substantiate the claim that a part of the expenses of such membership was incurred for business purposes, then it would seem that these latter expenses would be deductible. Further discussion of this particular aspect of the federal law will be found in a subsequent paragraph dealing with the deductibility of entertainment expenses.

Postgraduate Study.—The U. S. Court of Appeals, Second Circuit, in the case of *Coughlin v. Commissioner of Internal Revenue* (203 F. (2d) 307) held, on April 14, 1953, that the taxpayer, a lawyer, could deduct for federal income tax purposes expenses incurred by him in attending a postgraduate course on taxation. The government did not appeal this de-

cision, and the time within which an appeal could have been effected expired 90 days after the decision date. Tax counsel advises:

"The decision of the Circuit Court is not confined to lawyers. It equally applies to the practicing physician who attends postgraduate courses which are similarly designed to refresh his medical knowledge and to keep him informed of recent medical developments. Therefore, in computing his federal income tax a doctor may deduct the expenses of his attendance, namely, the cost of his tuition, travel, board, and lodging.

"However, it is by no means clear that the court's decision covers attendance at postgraduate courses which are designed to advance the doctor into a new area of his profession. For example, there is a good deal of doubt whether a general practitioner may deduct his expenses in attending a postgraduate course in order to specialize in surgery. But this would be the unusual case. Normally, a doctor attends a postgraduate course relevant to the field in which he is practicing and all the expenses which he so incurs are deductible by him."

Traveling Expenses.—Traveling expenses, including amounts paid for transportation, meals, and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

Entertainment Expenses.—The deductibility of entertainment expenses, when incurred for business purposes, has been upheld, as applied to an actor, in the case of *Blakmer v. Commissioner*, 70 F. (2d) 255. In the case of *Jacobson*, 6 T.C. 1048, the taxpayer was allowed a deduction of expenses incurred for entertaining clients and employees of his law firm. The deductibility of such expenses by an attorney came before the U. S. Tax Court in the case of *Clyde A. Armstrong v. Commissioner*, decided Aug. 29, 1947, 6 TCM 997. In a memorandum opinion rendered by Judge Oppen, this was said:

Taxpayer, a Pittsburgh attorney, became a member of the University Club and the Duquesne Club in order to have available facilities for the entertainment of his clients; his purpose in joining the clubs was not particularly to make contacts productive of new business. In 1942, 1943, and 1944 the Commissioner disallowed deductions representing club dues, but allowed 50% of the house bills incurred by taxpayer at each of the clubs during those years. The court finds that taxpayer used the club facilities not less than 50% of the time for entertaining clients and other purposes incident to the practice of his profession, and allows the deduction of dues to that extent.

In the December, 1948, issue of the *Medical Annals of the District of Columbia*, page 697, there was published correspondence that had passed between the secretary of the Medical Society of the District of Columbia and the Internal Revenue Agent in the Baltimore Division, Treasury Department, in which the latter stated that if entertainment expenses incurred by a physician have a direct relation to the production of income, and can be supported by the taxpayer, they will be taken into consideration in determining his net taxable income.

Directors of Internal Revenue in several jurisdictions have questioned the right of physicians to deduct entertainment expenses, contending that it is unethical for a physician to make expenditures of this character. The Judicial Council of the Association, in its report to the House of Delegates at the Los Angeles, 1951, meeting said in part:

"The Council does not consider such expenditures as *per se* unethical. There are circumstances under which a professional obligation may rest on a physician to entertain other physicians. It is a usual and necessary concomitant of the practice of medicine. It is certainly not an uncommon practice and is recognized by the profession generally as entirely proper and justifiable." This report was approved by the House of Delegates (*J. A. M. A.* 147:1686, Dec. 22, 1951).

Expenses Incurred by Members of the Auxiliary.—Two applications have been filed with the Office of the Commissioner of Internal Revenue, one on behalf of the American Medical Association and one on behalf of the Woman's Auxiliary, asking for a ruling on the deductibility of expenses incurred by members of the Auxiliary in attending official meetings. In each case the requested ruling was withheld for the principal reason that neither the Association nor the Auxiliary was a taxpayer whose tax liability would be affected by the ruling requested. In response to the petition of the Auxiliary, however, a communication from the Office of the Commissioner stated as follows:

"Since the question of whether the expenses incurred by the members of the Auxiliary in attending the conventions and other meetings are deductible under section 23(a)(1)(A) of the Internal Revenue Code depends upon the facts in each particular case, a general ruling applicable to all members of the Auxiliary may not be made.

"A taxpayer claiming the benefit of the deduction of such expenses must attach to his return a statement showing (1) the nature of the business in which engaged; (2) the number of days away from home during the taxable year on account of business; (3) the total amount of expenses incident to meals and lodging while absent from home on business during the taxable year; and (4) the total amount of other expenses incident to travel claimed as a deduction.

"Claims for deduction of such expenses must be substantiated, when required by the Commissioner, by evidence showing in detail the amount and nature of the expenses."

Automobiles.—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeur's wages, and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses; he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood. What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

Surgical Uniforms.—Amounts expended by surgeons for the purchase and maintenance of distinctive types of uniforms which are not adaptable to ordinary wear and which are required to be worn while on duty are deductible as ordinary and necessary business expenses.

MISCELLANEOUS

Contributions to Charitable Organizations.—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the directors of internal revenue or from other reliable sources. An individual taxpayer can deduct such contributions only to the extent that they do not exceed 20% of his adjusted gross income. The physician may not deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes. It has been held that blood donated by a person to a charitable institution for a transfusion, or to a blood bank, is not property and the fair market value of the blood is not deductible as a charitable contribution.

Bad Debts.—Physicians who make their returns on a cash receipts and disbursements basis, as most physicians do, cannot claim deductions for bad debts.

Taxes.—Taxes generally, either federal or state, are deductible by the person on whom they are imposed by law. Both real and personal property taxes are deductible; but so-called taxes, more properly assessments, paid for local benefits, such as street, sidewalk, and other like improvements, imposed because of and measured by some benefit inuring directly to the property against which the assessment is levied, do not constitute an allowable deduction from gross income. Physicians may deduct state gasoline taxes and state sales taxes. In some states sales taxes are imposed on the seller, but if they are passed on to the buyer the latter may deduct them.

State income and use taxes are deductible; federal income taxes are not. Federal import, excise, or stamp taxes are deductible only to the extent that they are attributable to business activities. State automobile license fees are deductible. If a state or local fee is imposed for regulatory purposes, and not to raise revenue, the fee may not ordinarily be deducted as a tax. If such fees, however, are classifiable as a business expense they are deductible as such. Annual registration fees imposed on physicians probably come within the category of regulatory fees and should be deducted as a business ex-

pense rather than as taxes. Local and state occupational taxes imposed on physicians are deductible either as taxes or as a business expense, depending on the purpose for which the tax is imposed.

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

Medical Expense.—A taxpayer may deduct amounts in excess of 5% of adjusted gross income expended for medical, dental and hospital expense for himself, his spouse or a dependent, not compensated for by insurance or otherwise, including amounts paid for health and accident insurance, according to a prescribed formula. This 5% limitation does not apply with respect to medical expenses for the care of the taxpayer or his spouse if either has reached the age of 65 before the close of the year. The law limits the deduction to a maximum of (a) \$1,250 if the taxpayer claims only one exemption; (b) \$2,500 if the taxpayer is a single person or if married and filing a separate return and claims more than one exemption; (c) \$2,500 if the taxpayers are married and file a joint return and claim two exemptions, \$3,750 if three exemptions are claimed and \$5,000 if four or more exemptions are claimed. It has been held that the cost of installing a stair seat elevator in a home, necessitated by a heart condition, does not constitute a deductible medical expense. Fees paid to qualified psychologists for therapeutic treatment are deductible as medical expenses. If a practical nurse is hired on the advice of a taxpayer's physician, the nurse residing in the taxpayer's home, her compensation is attributable to medical care and not to personal services. According to a ruling of the Bureau of Internal Revenue that part of the premium of a health and accident insurance policy that purchases insurance providing reimbursement to the insured for loss of earnings is not deductible as a medical expense.

Laboratory Expenses.—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes.—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums.—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits.—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

MEDICAL NEWS

ARKANSAS

Medicine and Crime Detection.—A dinner meeting for lawyers, physicians, F. B. I. men, police officers, judges, sheriffs, coroners, prosecuting attorneys, and others interested will be held Feb. 9, 6:30 p. m., at the Camden Hotel in Camden (plate charge, \$3). The meeting, which is sponsored by Dr. R. B. Robins of Camden, will be addressed by Dr. Charles P. Larson, associate clinical professor of pathology, University of Washington School of Medicine, Seattle, who will present an illustrated lecture "Crime Detection by Scientific Medicine." Dr. Larson is chairman of the committee on forensic pathology for the College of American Pathologists and during World War II was chief pathologist for the War Crimes Commission in Southern Germany. He is also director of the Tacoma Police Department Laboratory and pathologist for the Tacoma General Hospital.

ILLINOIS

Illinois Appoints Medical Dean.—Dr. Granville A. Bennett, professor of pathology, University of Illinois College of Medicine, Chicago, has been appointed dean of the college and will assume those duties in the spring. Dr. Roger A. Harvey, who has been acting dean since Jan. 1, 1953, will return full-time to his position as professor of radiology and head of the department, and radiologist in chief of the Research and Educational Hospitals, for which Dr. Bennett presently serves as pathologist in chief. Dr. Bennett, who has been head of the department of pathology since 1944, is chief editor of the *A. M. A. Archives of Pathology*. He is consultant to the Armed Forces Institute of Pathology, consultant in pathology to La Rabida Jackson Park Sanitarium, Chicago, a member of the council of the American Association of Pathologists and Bacteriologists, and a member of the executive committee of the Institute of Medical Education. Before coming to Chicago in 1944, he was head of the department of pathology and bacteriology at Tulane University of Louisiana School of Medicine, New Orleans, and taught at Harvard Medical School, Boston, from 1927 to 1943. Dr. Bennett's research interests have been concerned chiefly with diseases of the skeletal system. He is a past president of the Chicago Pathological Society, the Illinois Society of Pathologists, the American Association of Medical Museums, and the New England Pathological Society and is a fellow of the College of American Pathologists.

Chicago

Course in Bronchoesophagology.—This course will be given by the University of Illinois College of Medicine March 22 to April 3 under the direction of Dr. Paul H. Holinger. Registrants should contact the department of otolaryngology, University of Illinois College of Medicine, 1853 W. Polk St., Chicago 12.

Meeting of Neurosurgeons.—The Interurban Neurosurgical Society will present the following program, which will be heard by invitation only, at 9 a. m. Feb. 13 at the University Club of Chicago:

- Anterior Choroïdal Artery Occlusion in Parkinsonism, Irving S. Cooper, Bronxville, N. Y.
- Pressures in the Cervical Carotid and Intracranial Arteries, William H. Sweet, Boston.
- Concept of Temporal Lobe Epilepsy, Herbert H. Jasper, Montreal, Canada.
- Craniopagus, Oscar Sugar, Chicago.

Round-Table Discussions on Cancer.—A series of round-table discussions on cancer is being presented by the University of Chicago under the auspices of the Cancer Coordinator's Pro-

gram. Students, faculty, residents, and the profession-at-large are cordially invited to attend. The following sessions will be held Monday afternoons at 5 o'clock in Billings Hospital, Room P-117:

- Feb. 8, Cancer of the Breast.
- Feb. 15, Tumors of the Uterus and Ovary.
- Feb. 22, Cancer of the Cervix.
- March 1, Tumors of the Mouth, Tongue, Jaw, and Salivary Glands.
- March 8, Tumors of the Bladder, Prostate, and Testes.
- March 15, Tumors of the Small Bowel, Colon, and Rectum.

MICHIGAN

State Medical Election.—At the annual meeting in Grand Rapids Dr. Leroy W. Hull, Detroit, assumed the presidency of the Michigan State Medical Society; Dr. Robert H. Baker, Pontiac, was named president-elect; Dr. L. Fernald Foster, Bay City, secretary; and Dr. William A. Hyland, Grand Rapids, treasurer.

Symposium on Office Procedures.—The Symposium on Office Procedures, Feb. 10, at the Sheraton-Cadillac Hotel, Detroit, is open to anyone conducting an office practice. The topics include "Anesthesia in the Office," "Cardiology for the General Practitioner," "Pediatric Immunization Procedures," "Peri-vascular Diseases," "Industrial Surgery," "O. B. and Gyn. in the Office," and "Laboratory Procedures." The panel system will be used, with questions from the audience at the end of the morning and afternoon sessions. Dr. Arch Walls, Detroit, will serve as moderator in the morning and Dr. Ralph Johnson, Detroit, in the afternoon. Dr. William Bromme, Detroit, will be the speaker at the complimentary luncheon. Dr. Francis P. Rhoades, Detroit, chairman, educational committee, Wayne County Academy of General Practice, has arranged this medical seminar with the cooperation of the Lederle Laboratories. Formal postgraduate credits will be given to members of the American Academy of General Practice for attendance. A card party with table prizes and refreshments has been arranged from 2 to 5 o'clock at the Sheraton-Cadillac for the wives of the physicians attending the symposium. A cocktail party for physicians and their wives will be held at the close of the afternoon session.

NEW YORK

Historical Documents Wanted.—Dr. J. Homer Cudmore, historian of the Medical Society of the County of New York, urges all members who have historical diaries, letters, or other documents on the practice of medicine and the New York County Medical Society in earlier years to communicate with him at the offices of the society, 2 E. 103rd St. (phone ATwater 9-7305). The material is for use in a proposed history of the society.

Meeting on Antihypertensive Drugs.—The New York Society for Circulatory Diseases will meet at 8:30 p. m., Feb. 9, at the New York Academy of Medicine Building for a pharmacological and clinical evaluation of the newer antihypertensive drugs. Among the speakers will be: Dr. Rudolph E. Fremont, chief, cardiovascular department, Veterans Administration Hospital, Brooklyn, and Dr. Milton Mendlowitz, associate attending physician, Mount Sinai Hospital, New York. There will be a panel discussion. Dr. Simon Dack, New York, will preside.

Annual Fracture Day.—The New York and Brooklyn Regional Committee on Trauma of the American College of Surgeons will present the 19th annual Fracture Day Feb. 13 at the Lenox Hill Hospital, 111 E. 76th St., New York. At 10:30 a. m. Dr. John L. Madden, New York, will conduct a symposium on vascular trauma in which Dr. Lester Blum, New York, will give a case presentation on specific arterial injuries; Dr. Jere W. Lord, New York, will present "Arterial Grafts and Their Use Relative to Blood Vessel Trauma"; and Dr. Gerald H. Pratt, New York, will discuss "The Surgical Management of

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Blood Vessel Trauma, Both Early and Late." At 2:30 p. m. Dr. Robert H. Kennedy, New York, will serve as conductor for a symposium on intramedullary nailing of fractures. Fractures of the forearm will be discussed by Dr. Frederick H. Vom Saal, New York; fractures of the humerus by Dr. Robert Green, Philadelphia; fractures of the tibia by Dr. Frederick M. Marek, New York; and fractures of the femur by Dr. Sawnie R. Gaston, New York. Other presentations include:

Ancillary Care of the Fracture Patient, Nutrition, Electrolyte Balance, etc., James A. Nicholas, New York.
Treatment of Acute Facial Trauma, Arthur J. Barsky, New York.
Indications and Contraindications for Early Use of Artificial Hip Prosthesis, Frederick R. Thompson, New York.
Management of Bone Cysts, J. Earl Miles, Brooklyn.
Early Recognition of Impending Nonunion, William H. Cassebaum, New York.

New York City

Lecture on Congenital Heart Disease.—Dr. Thomas F. McDermott Jr., professor of anesthesiology, Georgetown University Medical Center, Washington, D. C., will address the anesthesiology staff of the Columbia-Presbyterian Medical Center Feb. 11 on congenital heart disease.

Memorial to Joseph Goldberger.—A film depicting the life of the late Dr. Joseph Goldberger and his successful struggle to combat and cure pellagra was recently previewed at the New York University-Bellevue Medical Center at a private showing for Mrs. Mary Farrar Goldberger, wife of the late Dr. Goldberger; members of the Goldberger family; and faculty of the college. Dr. Currier McEwen, dean of the college, accepted a copy of the film for use by students of the college from the DuPont Company. The preview was held in advance of the public performance that appeared on "Cavalcade of America" Jan. 12.

In recognition of Dr. Goldberger's contributions to medical science, a laboratory, named in his honor, for the investigation of nutritional and metabolic diseases is now being planned at his alma mater, the New York University College of Medicine. The size and equipment of this laboratory, to be located in the new medical science building of New York University-Bellevue Medical Center, will depend on the funds subscribed to construct and support it.

OHIO

Narcotic Violation.—Dr. Milan D. Chepko, Toledo, pleaded guilty in the U. S. District Court at Toledo to a charge of violating the federal narcotic law and on Nov. 10, 1953, was sentenced to serve a term of two years.

Steubenville Academy Series.—In its series of monthly lectures the Academy of Medicine, meeting in the Fort Steuben Hotel, Steubenville, Feb. 9, will hear "Surgical Aspects of Heart Disease" by Dr. Harold Feil, Cleveland. Physicians, interns, and graduate nurses are invited. Information may be obtained from Dr. Edward B. Weinman, secretary-treasurer, National Exchange Bank Building, Steubenville.

PENNSYLVANIA

Society News.—The Pennsylvania Public Health Association recently elected Dr. Mildred C. J. Pfeiffer, Philadelphia, as president, Dr. J. Thomas Millington, Kingston, Pa., president-elect, Dr. Merl G. Colvin, Williamsport, vice-president, and Robert Conn, Harrisburg, Pa., secretary-treasurer.—The Medical Society of the State of Pennsylvania, which annually presents testimonial plaques to 100-year-old residents of the state, requests that the names, addresses, and dates of birth of residents who will become centenarians during 1954 be sent to the society headquarters, 230 State St., Harrisburg. Hand-lettered, framed testimonials will be presented to the centenarians by officers of the medical society of the county in which they live.—On Feb. 16 Dr. Louis A. Krause, professor of medicine, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, will discuss "Medicine and the Bible" before the Allegheny County Medical Society meeting (225 Jenkins Building, Pittsburgh).

Pittsburgh

Residencies in Allergy.—The Medical Center, University of Pittsburgh School of Medicine, and the U. S. Veterans Hospital, Pittsburgh, announce several openings for a one year residency in allergy. This includes clinical and laboratory training as well as teaching experience. Salary, \$1,500-\$3,300 per annum. Address inquiries to Dr. Leo H. Crip, The Bigelow, Pittsburgh 19.

SOUTH CAROLINA

Deaths from Rabies.—According to the U. S. Public Health Service, a boy who was bitten severely on the face by a dog that was proved rabid by laboratory examination was given an antirabies vaccination the same day, was admitted to a hospital on the day of the last vaccination, but died two days later. The rabies virus was isolated. On recommendation of a family physician, a girl who had played with a dog that was killed the first week in December but was not examined for rabies was given antirabies treatment although she had not been bitten. Treatment was begun Dec. 8, 1953, and on the ninth day the child was admitted to a hospital, where a diagnosis of rabies encephalitis was made. She died five days later.

TENNESSEE

Society News.—The Nashville Surgical Society recently elected Dr. Eugene M. Regen, president; Dr. Cleo M. Miller, vice-president; and Dr. Ray O. Fessey, secretary-treasurer.—Dr. Jewell M. Dorris has been elected president of the Memphis Surgical Society. Dr. Robert M. Pool is vice-president, and Dr. J. Malcolm Aste, secretary-treasurer.

Meeting of Ophthalmologists and Otolaryngologists.—The Memphis Society of Ophthalmology and Otolaryngology will hold its annual convention Feb. 6-8. Guest speakers will be Drs. Daniel B. Kirby, Charles A. Perera, and John M. Converse, all of New York; Dr. Lewis F. Morrison, San Francisco; Dr. Jerome A. Hilger, St. Paul; and Dr. Kenneth C. Swan, Portland, Ore.

WISCONSIN

Meeting on Heart Disease.—Through a grant from the Lucy Ann Droessel memorial fund, a meeting on heart disease will be held Feb. 11 under the cosponsorship of the Medical Society of Milwaukee County and the Wisconsin Heart Association. The speakers will be Drs. James C. Paterson, Collip Medical Research Laboratory, University of Western Ontario, London, Canada; Nelson W. Barker, Mayo Clinic, Rochester, Minn.; and Jeremiah Stampler, Michael Reese Hospital, Chicago. All Wisconsin physicians are invited.

Scholarships for Course at Trudeau School.—The Wisconsin Anti-Tuberculosis Association offers two scholarships to Wisconsin physicians for a four week course in tuberculosis and other chronic chest diseases. Scholarships, which are open to recent graduates of approved medical schools, include a tuition fee of \$100, transportation to Saranac Lake, N. Y., and return, and full maintenance (a total of \$500, of which \$250 is to be returned to the Wisconsin Anti-Tuberculosis Association within five years). The course will be conducted by the Trudeau School of Tuberculosis at Saranac Lake, May 31 to June 25. Veterans desiring to take advantage of the G. I. Bill of Rights rather than the scholarships should clear their registration with the Veterans Administration before the session opens. Application for scholarship must be in the hands of the committee by March 1. For application blank, write to Dr. Arthur A. Pleyte, Wisconsin Anti-Tuberculosis Association, 1018 N. Jefferson St., Milwaukee 2.

HAWAII

Society News.—At a recent meeting of the Honolulu Pediatric Society, the following officers were elected: Dr. John H. Peyton, president; Dr. Goonzo Yamashita, recording secretary; and Dr. Howard M. Sexton, corresponding secretary-treasurer.

GENERAL

Association of Public Health Physicians.—The Committee to Promote the Formation of an American Association of Public Health Physicians will meet at the Palmer House in Chicago at 9:30 a. m., Feb. 6, to adopt a constitution and bylaws, elect tentative officers, and take other steps incident to the organization of the association. It is anticipated that the first annual meeting will be held in Buffalo during the meeting of the American Public Health Association, Oct. 11-15.

Meeting of University Surgeons.—The Society of University Surgeons will hold its annual meeting Feb. 11-13 in Rochester, N. Y. The Thursday sessions will be held in Whipple Auditorium, University of Rochester School of Medicine and Dentistry, for which busses will leave the Sheraton Hotel at 9 a. m. The Thursday session will conclude at 4:10 p. m. with a demonstration of cinefluorography. A dinner dance will be held at the Genesee Valley Club, 7 p. m. Friday meetings will be conducted at the Starlite Roof of the Sheraton Hotel. At 7 p. m. cocktails for members and their wives will precede dinner for members (in dinner jackets) in the ballroom, and a dinner for wives in the Green Room. The sessions will end on Saturday at noon, the morning session being opened with a presentation on metabolic alterations in surgical patients, in which the influence of peritonitis on nitrogen, carbohydrate, electrolyte, and water balance will be discussed.

Meeting of Pathologists in Detroit.—A joint meeting of the North Central Region of the College of American Pathologists and the Michigan Pathological Society will be held at Henry Ford Hospital, Detroit, Feb. 13. A round table on cytology of the female genital tract will be presented at 11:30 a. m. by Gardner M. Riley, Ph.D., Ann Arbor, Mich., and Drs. James W. Reagan, Cleveland, Israel Davidsohn, Chicago, Arthur T. Hertig, Boston, and Donald C. Beaver, Detroit. At 2 p. m. Dr. Hertig will serve as moderator for a seminar "Obstetrical and Gynecological Pathology." Other presentations include:

- Silver Stain in the Cytologic Diagnosis of Uterine Cancer, Gardner M. Riley, Ph.D., Ann Arbor, Mich.
- Cellular Changes in Uterine Cancers and Associated Epithelial Lesions, James W. Reagan, Cleveland.
- Immunologic and Serologic Aspects of Hemolytic Disease of the Newborn. The Birth of a New Discipline: Immunohematology, Israel Davidsohn, Chicago.

The banquet will be held at 6 p. m.

World Heart Congress in Washington.—A combined meeting of the 2nd World Congress of Cardiology and the 27th Scientific Sessions of the American Heart Association, the first international medical gathering of its kind in the United States, will be held Sept. 12-17 in Washington, D. C., under the presidency of Dr. Paul D. White, Boston. Membership in the congress is open to all members of the affiliated national cardiac societies and associations of the world, and to other physicians and scientific workers of comparable status residing in countries where national cardiac societies are not as yet established. Nonmembers are invited to attend the congress by special invitation from the Organizational Committee. Applications must be received at the congress office no later than March 1. Titles and abstracts of papers from the United States and Canada must be received on or before April 1 by Dr. Charles D. Marple, medical director, American Heart Association, 44 E. 23rd St., New York 10. Contributors from countries outside the United States are required to submit titles with abstracts, which may be accompanied by translations in French, Spanish or German, to the secretaries of their national cardiological societies as soon as possible, since the deadline for these to be received in the United States is March 1. A booklet containing detailed information may be obtained by writing to Dr. L. W. Gorham, Secretary-General, Second World Congress of Cardiology, 44 E. 23rd St., New York 10. Scientific and industrial exhibits have been planned. Industrial firms interested in presenting exhibits may communicate with Steven K. Herlitz, Exhibits Manager, 280 Madison Ave., New York 16.

Occupational Medicine Meeting in Richmond.—The American Academy of Occupational Medicine will hold its annual meeting at the John Marshall Hotel, Richmond, Va., Feb. 11-12. The morning session will open with presentation of "Use of Ascorbic Acid in Prevention of Heat Exhaustion" by Dr. Burton E. Field, Spruance Rayon Plant, Richmond, Va., and "Abnormal Physiology of the Kidney and Liver in Acute Chemical Toxemia" by Dr. John H. Foulger, director of medical research, E. I. duPont de Nemours & Company, Wilmington, Del. It will close with "Use of the Chemical Proof Air Suit" by Dr. Edgar E. Evans, medical supervisor, duPont Chambers Works, Deepwater, N. J., which will be preceded by "The Pathology of Deafness Due to Noise" by Stacy R. Guild, Ph.D., associate professor of otology, Johns Hopkins Hospital, Baltimore. Dr. Frederick W. Dersheimer and Dr. Gerald Gordon, duPont Medical Division, Wilmington, Del., will open the afternoon session with "Effective Discipline Promotes Mental Health," which will be followed by a presentation, "Dr. Jones Esq. Appears for the Defense" (Rx vs. Lex), by Carl Geuther of the legal department, E. I. duPont de Nemours & Company. The business meeting, 4:30 p. m., will be preceded by "The Place of Manipulation Therapy in Medicine with Emphasis on Low Back Pain," by John McMillan Mennel, M.B., Richmond. Friday, 9 a. m., busses will leave the John Marshall Hotel for the Spruance Plant auditorium, where the program will be continued. Luncheon at the plant cafeteria will be followed by a tour through the rayon and cellophane plants. The A. L. Robins Pharmaceutical Company of Richmond will be hosts Saturday for a trip to Williamsburg, if sufficient members are interested. The bus will leave around 9 a. m. and return to Richmond between 3 and 4 p. m.

Mid-South Postgraduate Assembly.—The Mid-South Postgraduate Medical Assembly will hold its annual session at the Hotel Peabody, Memphis, Tenn., Feb. 9-12. Guest speakers and their first presentations include:

- Gallbladder Disease, Warren H. Cole, Chicago.
- Serious Eye Diseases in Infants, Kenneth C. Swan, Portland, Ore.
- Management of Cardiac Arrest (colored motion picture), Henry Swan II, Denver.
- Curable Forms of Heart Disease, A. Carlton Ernestine, Cleveland.
- Hemorrhage in Pregnancy, Charles E. Galloway, Evanston, Ill.
- Abuse of the Anticlotics in Chronic Running Ears, Especially in Children, Lewis F. Morrison, San Francisco.
- Management of Disabling Pain in the H.P., Joseph S. Barr, Boston.
- Advances in the Field of Pediatrics, Sydney S. Gellis, Boston.
- Prevention and Treatment of Complications of Long Term Diabetes, Alexander Marble, Boston.
- Simplicity of Biopsy in the Diagnosis of Cancer, Everett D. Sugarbaker, Jefferson City, Mo.
- Treatment of Inoperable Carcinoma of the Prostate, Gershom J. Thompson, Rochester, Minn.
- Clinical Foundation of Chest Radiology, Robert R. Newell, San Francisco.
- Brain Tumors, Bronson S. Ray, New York.
- Clinical Aspects of Obstruction of the Small Bowel, James D. Rives, New Orleans.
- Problem of Aged Parents, Edward J. Stieglitz, Washington, D. C.
- Metabolic Concept of Gynecological Care, Hugh G. Hamilton, Kansas City, Mo.
- Rationale of Physiologic Stomach Rest in the Therapy of Peptic Ulcer and the Role of the Newer Pharmacologic Agents, Henry L. Bockus, Philadelphia.
- Clinical Features and Diagnosis of the Nonpyogenic Meningitides, Theodore E. Woodward, Baltimore.
- Cerebral Changes in the Newborn, James B. Arey, Philadelphia.

An informal dinner will be held in the ballroom, Thursday, 7:30 p. m., where "The Incredible Dr. Jaks" will discuss "Curiosities of the Mind."

The Mid-South Postgraduate Nurse Anesthetists Assembly and the Tennessee Association of Nurse Anesthetists will hold their convention simultaneously at the Hotel Peabody. Their guest speakers include Drs. Arey, Barr, Galloway, Gellis, Hamilton, Marble, Newell, Ray, Sugarbaker, and Henry Swan. Presentations will also be made by Drs. Robert E. Lawson, Leonard J. Vernon, Mary F. Poe, Memphis, Tenn., and John Adriani, New Orleans.

Scholarship in Lipreading.—Competition for the Kenfield memorial scholarship, awarded annually by the American Hearing Society to a prospective teacher of lipreading, will open March 1. Winner of the annual award is entitled to take

a teaching training course in lipreading from any school or university in the United States acceptable to the teachers committee. The scholarship is to be used within one year from the date of award. Graduation from college with a major in education, psychology, and/or speech is a requirement. Specifications for a hard of hearing contestant include 30 hours of private instruction in lipreading from an approved teacher or 60 hours of lipreading in public school classes under an approved teacher. Rules for competition state that an applicant shall plan to teach lipreading with or without other types of speech or hearing therapy. Application blanks may be obtained by writing to the society's national headquarters, 817-14th St., N.W., Washington 5, D. C., and must be returned by May 1 to Mrs. Eleanor C. Ronnei, care of the New York League for the Hard of Hearing, 480 Lexington Ave., New York 17.

CANADA

Charles H. Best Institute.—The new Charles H. Best Institute at the University of Toronto was officially opened Sept. 15, 1953, when Sir Henry Dale, Nobel laureate and chairman of the scientific advisory committee to the British government, turned a golden key in the door of the new building. The institute, which will house the teaching facilities for the department of physiology, will provide greatly increased research facilities for this department and for the associated Banting

Charles H. Best Institute, University of Toronto.

and Best department of medical research. Among those receiving honorary degrees at a special convocation preceding the opening, were Detlev W. Bronk, Ph.D., director of the Rockefeller Institute for Medical Research, New York; Dr. Elliott P. Joslin, Boston; and Dr. Wilder G. Penfield, Montreal.

LATIN AMERICA

Congress of Physical Medicine.—The Latin-American Congress of Physical Medicine will hold its annual meeting in Medellin, Colombia, Feb. 15-20, after which a tour will be made to Bogota, Barranquilla, and Montega Bay, Jamaica. The trip will end Feb. 28. Transportation at a special all-inclusive rate, via plane or steamship, will be available to those participating. Registration must be made through Dr. Cassius Lopez de Victoria, Executive Director, 176 E. 71st St., New York 21.

Congress of Otorhinolaryngology.—The third Latin American Congress of Otorhinolaryngology will take place at Caracas, Venezuela, Feb. 21-25 under the auspices of the government of Venezuela and the ministry of public health and social aid, with the cooperation of the National Academy of Medicine, the Venezuela Society of Otorhinolaryngology and Ophthalmology, the Venezuela Society of Surgery, and the National Society of Otorhinolaryngology. Topics to be discussed include incidents and accidents of anesthesia and otorhinolaryngology, cancer of the rhinopharynx, surgery of malignant tumors of the pharynx and larynx, and esophagogastric lesions treated by cortisone or corticotropin (ACTH).

FOREIGN

Industrial Meeting in India.—The Society for the Study of Industrial Medicine will hold its annual meeting in Calcutta, India, Feb. 4-6. The society, established six years ago, has a membership of about 450 and branches in Calcutta, Bombay, Madras, and Ahmedabad.

Gynecologic Meeting Place Changed.—The Assises Françaises de Gynécologie, originally scheduled for Dijon, will be held in Paris, July 22-24, to discuss "The Treatment of Genital Prolapse." For information and registration, write to the Secretary General, Robert Senechal, 31 Rue Raynouard, Paris 16e.

Ophthalmological Congress.—The annual congress of the Ophthalmological Society of the United Kingdom will be held at the University of Durham, Newcastle-on-Tyne, England, April 22-24. The subject for discussion will be "Inflammatory Vascular Diseases Affecting the Eyes." There will be also three short symposia on the following subjects: "Cyclodialthermy," "Changes in the Incidence of the Eye Affections of Coal Miners in the Past 25 Years," and "Gonioscopy."

Persian Gulf Medical Society.—The Persian Gulf Medical Society, which held its second annual meeting Dec. 7-8, 1953, chose as president-elect Dr. Neal J. Conan Jr., head of the department of internal medicine, Aramco, Dhahran, Saudi Arabia, and clinical professor of internal medicine, American University of Beirut. The program, which opened with the report "Current Research at Harvard School of Public Health on Major Health Problems of the Middle East" by Dr. John C. Snyder, professor of microbiology, Harvard School of Public Health, Boston, included discussions on surgical treatment of cutaneous leishmaniasis and of hydatid disease, treatment of typhoid fever with thiocymetin, surgical aspects of gastrointestinal tuberculosis, drug prophylaxis against amebiasis, and the injection treatment of hernia. The next annual meeting will be held in December on Bahrain Island.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

ANNUAL CONGRESS ON INDUSTRIAL HEALTH, Brown Hotel, Louisville, Ky., Feb. 24-25. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago 10, Secretary.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE, Palmer House, Chicago, Feb. 7-9. Dr. Edward L. Turner, 535 N. Dearborn St., Chicago 10, Secretary.

NATIONAL CONFERENCE ON RURAL HEALTH, Baker Hotel, Dallas, Texas, Mar. 4-6. Mrs. Arline Hibbard, 535 N. Dearborn St., Chicago 10, Secretary.

AERO MEDICAL ASSOCIATION, Hotel Statler, Washington, D. C., March 29-31. Dr. Thomas H. Sutherland, P. O. Box 26, Marion, Ohio, Secretary.

AMERICAN ACADEMY OF FORENSIC SCIENCES, Drake Hotel, Chicago, Feb. 25-27. Prof. Ralph F. Turner, Michigan State College Dept. of Police Administration, East Lansing, Mich., Secretary.

AMERICAN ACADEMY OF GENERAL PRACTICE, Cleveland, March 22-25. Mr. Mac F. Cahal, 406 West 34th St., Kansas City 2, Mo., Executive Secretary.

AMERICAN ACADEMY OF OCCUPATIONAL MEDICINE, John Marshall Hotel, Richmond, Va., Feb. 11-12. Dr. Leonard J. Goldwater, 600 W. 168th St., New York 32, Secretary.

AMERICAN HEART ASSOCIATION, Conrad Hilton Hotel, Chicago, April 1-4. Dr. William H. Bunn, 44 East 23d St., New York 10, Secretary.

AMERICAN ORTHOPSYCHIATRIC ASSOCIATION, Hotel Commodore, New York, March 11-13. Dr. Marion F. Langer, Room 210, 303 Lexington Ave., New York 16, Executive Secretary.

AMERICAN PROTESTANT HOSPITAL ASSOCIATION, Palmer House, Chicago, Feb. 10-12. Mr. Albert G. Hahn, Protestant Deaconess Hospital, Evansville, Ind., Executive Secretary.

AMERICAN PSYCHOSOMATIC SOCIETY, Jung Hotel, New Orleans, March 27-28. Dr. Theodore Lidz, 333 Cedar St., New Haven 11, Conn., Secretary.

AMERICAN RADIUM SOCIETY, The Homestead, Hot Springs, Va., March 14-16. Dr. Robert E. Fricke, 102 Second Ave. S.W., Rochester, Minn., Secretary.

CENTRAL SURGICAL ASSOCIATION, Statler Hotel, Detroit, Feb. 18-20. Dr. Robert M. Zollinger, University Hospital, Columbus 10, Ohio, Secretary.

CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE, Palmer House, Chicago, March 2-5. Dr. Maurice M. Hoeltgen, 86 East Randolph St., Chicago, Secretary.

DALLAS SOUTHERN CLINICAL SOCIETY, Dallas, March 15-18. Dr. T. Haynes Harvill, 433 Medical Arts Bldg., Dallas 1, Texas, Secretary.

EASTERN SURGICAL SOCIETY, Boston, March 26-27. Dr. J. William Hinton, 130 East 79th St., New York, Secretary.

MICHIGAN CLINICAL INSTITUTE, Sheraton-Cadillac Hotel, Detroit, March 10-12. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Mich., Secretary.

MID-SOUTH POST GRADUATE MEDICAL ASSEMBLY, Hotel Peabody, Memphis, Tenn., Feb. 9-12. Dr. Thurman Crawford, 869 Madison Ave., Memphis, Tenn., Secretary.

NATIONAL CONFERENCE ON CARE OF THE LONG-TERM PATIENT, Edgewater Beach Hotel, Chicago, March 18-20. Dr. Dean W. Roberts, 615 N. Wolfe St., Baltimore 5, Director.

NATIONAL CONFERENCE ON TRICHINOSIS, A. M. A. Headquarters, Chicago, March 1. Dr. S. E. Gould, Wayne County General Hospital, Eloise, Mich., Chairman.

NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS, Jefferson Hotel, St. Louis, March 10-12. Dr. F. M. Foote, 1790 Broadway, New York 19, Executive Director.

PACIFIC NORTHWEST SOCIETY OF PLASTIC AND RECONSTRUCTIVE SURGEONS, Seattle, April 3. Dr. E. E. Banfield, Medical Arts Bldg., Tacoma 2, Wash., Secretary.

REGIONAL MEETINGS, AMERICAN COLLEGE OF PHYSICIANS:

TOPEKA, KANS., March 19. Dr. William C. Menninger, 3617 West 6th Ave., Topeka, Kansas, Governor.

RICHMOND, VA., Feb. 25. Dr. Charles M. Caravati, 807 West Franklin St., Richmond 20, Va., Governor.

SOUTHERN CALIFORNIA, Riverside, Feb. 13-14. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

SECTIONAL MEETINGS, AMERICAN COLLEGE OF SURGEONS:

FRENCH LICK SPRINGS, Indiana, French Lick Springs Hotel, March 15-17. Dr. Carl H. McCaskey, 20 N. Meridian St., Indianapolis 4, Chairman.

MONTREAL, CANADA, Mount Royal Hotel, March 31-April 2. Dr. Harry S. Morton, 900 Sherbrooke St., West, Montreal, Canada, Chairman.

OMAHA, NEB., Hotel Fontenelle, March 1-4. Dr. Earl A. Connolly, 107 South 17th St., Omaha, Chairman.

RENO, NEV., Riverside Hotel, Feb. 25-26. Dr. Kenneth F. Maclean, 120 N. Virginia St., Reno, Nev., Chairman.

SOCIETY OF UNIVERSITY SURGEONS, Sheraton Hotel, Rochester, N. Y., Feb. 11-13. Dr. C. Rollins Hanlon, 1325 South Grand Blvd., St. Louis, Secretary.

SOUTHEASTERN ALLERGY ASSOCIATION, Dinkler-Plaza Hotel, Atlanta, Ga., March 25-27. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 1, S. C., Secretary.

SOUTHEASTERN SURGICAL CONGRESS, Tutwiler Hotel, Birmingham, Ala., March 8-11. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta, Ga., Secretary.

WESTERN SOCIETY OF ELECTRO-ENCEPHALOGRAPHY, Del Monte Lodge, Pebble Beach, Calif., March 7-8. Dr. Sylvester N. Berens, 902 Boren Ave., Seattle, Secretary.

FOREIGN AND INTERNATIONAL

ASSOCIATION OF SURGEONS OF GREAT BRITAIN AND IRELAND, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

BRITISH MEDICAL ASSOCIATION, Glasgow, Scotland, July 1-9, 1954. Dr. A. Macrae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

CANADIAN MEDICAL ASSOCIATION, Vancouver, B. C., Canada, June 14-18, 1954. Dr. T. C. Routley, 244 St. George St., Toronto 5, Ont., Canada, General Secretary.

CONFERENCE OF INTERNATIONAL UNION AGAINST TUBERCULOSIS, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

CONGRESS OF INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF BLINDNESS, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

EUROPEAN SOCIETY OF CARDIOVASCULAR SURGERY, Edinburgh, Scotland, July 9-10, 1954. For information address: Mr. A. J. Slessor, Department of Surgery, University New Building, Edinburgh 8, Scotland.

HEALTH CONGRESS OF THE ROYAL SANITARY INSTITUTE, Scarborough, England, April 27-30, 1954. Mr. P. Arthur Wells, Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1, England, Secretary.

INTERNATIONAL ANESTHESIA RESEARCH SOCIETY, Los Angeles, Calif., U. S. A., Oct. 4-7, 1954. For information write: Dr. T. H. Seldon, 102-110 Second Avenue S.W., Rochester, Minn., U. S. A.

INTERNATIONAL CANCER CONGRESS, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

INTERNATIONAL CONFERENCE ON THROMBOSIS AND EMBOLISM, Basle, Switzerland, July 20-24, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

INTERNATIONAL CONGRESS OF CLINICAL PATHOLOGY, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A. Moore, Washington University School of Medicine, St. Louis 10, Mo., U. S. A., Chairman, Committee on Arrangements.

INTERNATIONAL CONGRESS ON DISEASES OF THE CHEST, Barcelona, Spain, Oct. 4-8, 1954. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Ill., U. S. A., Executive Secretary.

WORLD MEDICAL ASSOCIATION, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Examination. Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

ARKANSAS: * Examination. Little Rock, June 10-11. Sec., Dr. Joe Verser, Harrisburg. *Eclectic.* Little Rock, June 11-12. Sec., Dr. O. L. Atkinson, 2528 Central Ave., Hot Springs National Park.

CALIFORNIA: Written. Los Angeles, March 15-18; San Francisco, June 21-24; San Diego, Aug. 23-26; Sacramento, Oct. 18-21. *Oral.* Los Angeles, March 13; San Francisco, June 19; San Diego, Aug. 21; Los Angeles, Nov. 20. *Oral and Clinical Examination for Foreign Medical School Graduates.* Sec., Dr. Louis E. Jones, 1020 N Street, Sacramento.

COLORADO: * Examination. Denver, June 8-9. Final date for filing applications is May 8. *Reciprocity.* Denver, April 13. Final date for filing applications is March 13. Exec. Sec., Mrs. Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

CONNECTICUT: * Examination. Hartford, March 9-10. Secretary to the Board, Dr. Creighton Barker, 160 St. Roman St., New Haven. *Homeopathic.* Derby, March 9-10. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

DISTRICT OF COLUMBIA: * Examination. Washington, May 10-11. Deputy Director, Mr. Paul Foley, Department of Occupations and Professions, 1740 Massachusetts Ave., N.W., Washington, D. C.

FLORIDA: * Examination. Jacksonville, June 27-29. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami.

GEORGIA: Examination and Reciprocity. Atlanta and Augusta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

GUAM: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agaña.

ILLINOIS: Examination and Reciprocity. Chicago, April 6-8; June 22-24, and Oct. 5-7. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

INDIANA: Examination. Indianapolis, June 16-18. Exec. Sec., Miss Ruth V. Kirk, 538 K of P Bldg., Indianapolis.

IOWA: * Examination. Iowa City, June 14-16. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

KANSAS: Examination and Reciprocity. Kansas City, June 9-10. Sec., Dr. O. W. Davidson, 872 New Brotherhood Bldg., Kansas City.

MAINE: Examination and Reciprocity. Portland, March 9-10. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Examination. Baltimore, June 15-18. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore 1.

MICHIGAN: * Examination. Detroit and Ann Arbor, June 1954. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

MISSISSIPPI: Examination and Reciprocity. Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Old Capitol, Jackson 113.

MISSOURI: Examination. Jefferson City, Feb. 18-19. *Reciprocity.* Jefferson City, Feb. 8. Exec. Sec., Mr. John A. Hailey, P. O. Box 4, Jefferson City.

MONTANA: Reciprocity. Helena, April 5. *Examination.* Helena, April 6-7. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

NEBRASKA: * Examination. Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

NEW HAMPSHIRE: Examination and Reciprocity. Concord, March 10. Sec., Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: Examination. Trenton, June 15-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: * Examination and Reciprocity. Santa Fe, April 12-13. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

NEW YORK: Examination. Albany, Buffalo, Syracuse and New York City, Feb. 16-19. Sec., Dr. Siles D. Ezell, 23 S. Pearl St., Albany.

OHIO: Examination. Columbus, June 14-16. *Reciprocity.* Columbus, April 13. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Examination. Oklahoma City, June 9-10. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

SOUTH DAKOTA: * Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

TENNESSEE: * Examination. Memphis, March 24-25. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

TEXAS: Examination and Reciprocity. Fort Worth, June 21-23. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Ft. Worth 2.

UTAH: Reciprocity. Salt Lake City, Feb. 16. Asst. Director, Mr. Frank E. Lees, 314 State Capitol Bldg., Salt Lake City 1.

VERMONT: Examination. Burlington, Jan. 28-30. Sec., Dr. F. J. Lawliss, Richmond.

VIRGINIA: Examination and Reciprocity. Richmond, June 16. Address: Virginia Board of Medical Examiners, 631 First St., S.W., Roanoke.

ALASKA: * On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARIZONA: Examination. Tucson, March 16. Sec., Mr. Herbert D. Rhodes, University of Arizona, Tucson.

COLORADO: Examination. Denver, March 3-4. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

CONNECTICUT: Examination. New Haven, Feb. 13. Address: State Board of Healing Arts, 52 Whitney Ave., New Haven 10.

FLORIDA: Examination. Gainesville, June. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

MICHIGAN: Examination. Detroit and Ann Arbor, Feb. 12-13. Sec., Mrs. Anne Baker, 410 W. Allegan St., Lansing 15.

NEBRASKA: Examination. Omaha, May 4-5. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln 9.

OKLAHOMA: Examination. Oklahoma City, April 16-17. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: Examination. Portland, March 6, June 5, Sept. 11 and Dec. 4. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

RHODE ISLAND: Examination. Providence, Feb. 10. Administrator, Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Examination. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Examination. Memphis, March 17-18. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

TEXAS: Examination. April 1954. Location determined by number of applicants from different sections of the state. Sec., Brother Raphael Wilson, C.S.C., 407 Perry-Brooke Bldg., Austin.

WISCONSIN: Examination. Madison, April 3 and June 5. Final date for filing application is March 26 and May 28. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

*Basic Science Certificate required.

DEATHS

Kirby, Daniel Bartholomew * New York City; born in Cleveland, April 12, 1891; Western Reserve University School of Medicine, Cleveland, 1916; professor emeritus of ophthalmology at New York University College of Medicine; specialist certified by the American Board of Ophthalmology, of which he was formerly chairman, and the American Board of Plastic Surgery; served during World War I; member of the American Academy of Ophthalmology and Otolaryngology, Harvey Society, American Ophthalmological Society, and the Association for Research in Ophthalmology; member of the ophthalmologic societies of Brazil, Argentina, Chile, Peru, Cuba, France, and Greece; fellow of the American College of Surgeons; served on the staffs of the New Rochelle (N. Y.) Hospital, St. Joseph's Hospital in Yonkers, Manhattan Eye and Ear Hospital, New York Eye and Ear Infirmary, and St. Clare's Hospital; formerly surgeon in chief, department of ophthalmology, Bellevue Hospital; author of "Surgery of Cataract" and others; died in Pelham Dec. 27, aged 62, of coronary disease.

Vander Veer, Edgar Albert * Albany, N. Y.; born in Albany, Sept. 29, 1873; Albany (N. Y.) Medical College, 1898; an Associate Fellow of the American Medical Association and member of its House of Delegates from 1911 through 1914 and in 1916; member of the founders group of the American Board of Surgery; member of the Industrial Medical Association and the American Surgical Association; fellow and one of the founders of the American College of Surgeons; past president of the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons and the New York State Society of Industrial Medicine; professor emeritus of surgery at his alma mater; on the courtesy staff, Albany Hospital; consulting surgeon, Anthony N. Brady Maternity Home, St. Peter's and Memorial hospitals in Albany, Benedictine Hospital in Kingston, and Memorial Hospital of Greene County, Catskill; died recently, aged 80, of pulmonary infarction and fracture of the left hip.

Altman, Morris Robert * New York City; Baltimore University School of Medicine, 1899; died recently, aged 76, of heart disease.

Bacher, Frank M., Oceanside, N. Y.; Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau, Germany, 1915; died in West Brentwood recently, aged 63, of acute cardiac dilatation.

Biscow, Harry Benjamin, New York City; University and Bellevue Hospital Medical College, New York, 1905; served as president of the Bronx Gynecological Society; affiliated with Sydenham Hospital and the Mount Sinai Hospital, where he died Oct. 27, aged 75, of leukemia.

Bundrant, William Clayborne, Klamath Falls, Ore.; University of Tennessee Medical Department, Nashville, 1910; died in the Hillside Hospital Oct. 10, aged 75, of myocarditis.

Campbell, Harry Lincoln * Medford, Mass.; Boston University School of Medicine, 1938; certified by the National Board of Medical Examiners; physician for the public schools; president of the Medford Medical Society; past president of the staff of Lawrence Memorial Hospital; died Oct. 14, aged 48, of carcinoma of the sigmoid with metastases to the vertebrae.

Fareed, Mirza Ameen Ullah * Santa Monica, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; served on the staff of the Hollywood Hospital in Los Angeles; died Dec. 3, aged 71.

Frankenthal, Maurice Albert * St. Louis; Johns Hopkins University School of Medicine, Baltimore, 1902; an Associate Fellow of the American Medical Association; died in Barnes Hospital Dec. 5, aged 76, of carcinoma of the colon.

Freeman, Will Loren, St. Charles, Mo.; Denver College of Medicine, 1893; served during World War I; formerly county coroner; died in St. Joseph Hospital Dec. 22, aged 84, of cerebral hemorrhage.

Gould, Dorsey Thomas, Waverly, Tenn.; University of Nashville Medical Department, 1902; served on the staff of the General Hospital in Nashville; died in St. Thomas Hospital, Nashville, Nov. 11, aged 82, of chronic myocarditis.

Hirsch, Abraham Albert, Kingsburg, Calif.; Bennett Medical College, Chicago, 1914; served as a civilian contract surgeon at U. S. Army Hospital, Camp Stoneman, Calif.; died in Spokane, Wash., Dec. 6, aged 61, of a heart attack.

Hodges, Thomas Luther * Bismarck, Ark.; Barnes Medical College, St. Louis, 1898 and 1899; died in Clark County Memorial Hospital in Arkadelphia, Dec. 3, aged 85, of coronary thrombosis.

Hosch, Jacob Frederick * Albany, Ore.; University of Oregon Medical School, Portland, 1905; formerly state legislator; served as mayor in Redmond and Bend; on the staffs of the Santiam Memorial Hospital in Stayton, and Albany General Hospital; died Dec. 5, aged 73, of carcinoma of the rectum and colon with metastasis to the lungs.

Keeler, Claude Charles, Albuquerque, N. M.; Central Medical College of St. Joseph, Mo., 1903; served during World War II; fellow of the American College of Surgeons; member of the American Trudeau Society; for many years affiliated with the Veterans Administration; formerly on the staff of the Veterans Administration Hospital in Fort Bayard; died in Laguna Beach, Calif., Oct. 18, aged 73, of coronary thrombosis.

Soriano, Fortunato, South Orange, N. J.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Naples, Italy, 1903; died in the Newark City Hospital Dec. 5, aged 72, of hypertensive cardiovascular disease.

Swarthout, Ellis Frank, Jensen Beach, Fla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; died Oct. 9, aged 75, of arteriosclerotic heart disease.

Taylor, Earle Ernest, Crichton, Ala.; University of Tennessee Medical Department, Nashville, 1904; died Oct. 8, aged 74, of coronary occlusion.

Taylor, Reu Spencer * Detroit; Detroit College of Medicine, 1906; on the staff of the Booth Hospital; died in the Providence Hospital Nov. 23, aged 77, of coronary occlusion.

Tutschulte, Ernest * Monroe, N. Y.; Cornell University Medical College, New York, 1899; Associate Fellow of the American Medical Association; died recently in Cornwall, aged 76, of coronary thrombosis and arteriosclerosis.

Watson, Clyde Emil, Morgantown, W. Va.; Johns Hopkins University School of Medicine, Baltimore, 1910; died Dec. 2, aged 74, of coronary heart disease.

Whitney, George W. * Auburn, N. Y.; Bellevue Hospital Medical College, New York, 1886; served on the staff of the Auburn City Hospital; died recently, aged 89, of cerebral hemorrhage and generalized arteriosclerosis.

Wiener, Solomon * New York City; Columbia University College of Physicians and Surgeons, New York, 1904; fellow of the American College of Surgeons; died Nov. 1, aged 71, of myocarditis.

Woldenberg, Samuel Charles * Washington, D. C.; Chicago Medical School, 1918; served during World War II; died Dec. 17, aged 59, of carcinomatosis.

Ziegler, Frederic Jay * Portland, Ore.; Jefferson Medical College of Philadelphia, 1905; for many years city physician; affiliated with Good Samaritan Hospital and the Providence Hospital, where he died Nov. 22, aged 75, of cancer.

GOVERNMENT SERVICES

NAVY

Reserve Officers Eligible for Active Duty for Training Courses.—Two active duty for training courses for Naval Reserve Medical Department officers have been scheduled for March, 1954. The courses will be of two weeks' duration each and will convene as follows:

Medicomilitary Training.—The third course in medicomilitary matters to convene at the Naval Medical School, National Naval Medical Center, Bethesda, Md., will be conducted March 8-20. The first week of the instruction period will be devoted to orientation in all phases of the medical reserve program of the Navy. Recent advances in military medicine and surgery, including aviation, submarine, and field medicine, will be presented. During the second week, there will be discussions of problems most likely to be encountered, and the recommended defensive techniques to be employed, by medical and dental officers against bacterial, chemical, and radiological activity. Reserve Medical, Dental, Medical Service, Nurse, and Hospital Corps officers residing in the 1st, 3rd, 4th, 5th, 6th, 8th, and 9th naval districts, and in the Potomac River naval command are eligible for this two weeks' active duty training. Interested officers should submit their request for 14 days' active training duty to the commandants of their naval districts. Naval districts listed above have been assigned quotas for this course.

Field Medicine.—Male Naval Reserve Medical Department officers residing in the 11th, 12th and 13th naval districts are eligible to attend a course in field medicine at the Marine Corps Base, Camp Pendleton, Calif., March 15. The course is designed to provide specialized training in field medicine for inactive Naval Reserve Medical, Dental, Medical Service, and Hospital Corps officers. Practical instruction in medical materiel logistics, preventive medicine in the field, treatment of battle casualties, and medical components of Fleet Marine Force units are included. The trainee will receive also practical instruction, including the use of small arms and items of individual field equipment, methods of protecting patients and medical personnel in assault, and march and bivouac routines. Eligible personnel interested in this course should submit their requests to the commandants of their respective naval districts. Bachelor officers quarters will be available for those attending the course in field medicine, and working uniform is required. Participation in these courses will not increase the Naval Reservist's vulnerability for orders to extended active duty.

PUBLIC HEALTH SERVICE

Venereal Disease Symposium.—The sixth annual Symposium on Recent Advances in the Study of Venereal Diseases will be held in the auditorium of the Department of Health, Education, and Welfare, Washington, D. C., April 29-30. The sessions are open to all interested physicians and workers in allied professions. These symposiums usually draw hundreds of persons from all parts of the country and are the occasion for exchange of the latest information by some of the most outstanding authorities. The topics to be discussed at this symposium will include basic and clinical research, serology, epidemiology, treatment, program operation, and professional education.

VETERANS ADMINISTRATION

Neuropsychiatric Meeting at North Little Rock.—The sixth annual neuropsychiatric meeting will be held at the Veterans Administration Hospital, North Little Rock, Ark., on Feb. 25-26. Among the guest lecturers will be Drs. Kenneth E. Appel, president, American Psychiatric Association, Philadelphia; Franz Alexander, director, Chicago Institute for Psychoanalysis;

Francis J. Braceland, psychiatrist in chief, Institute of Living, Hartford, Conn.; Dr. Richard L. Jenkins, chief, research section, psychiatry and neurology service, Department of Medicine and Surgery, Veterans Administration, Washington, D. C.; William Malamud, chairman, department of psychiatry and neurology, Boston University School of Medicine; Jules H. Masserman, Chicago; Henry G. Schwartz, professor of neurological surgery, Washington University, St. Louis; Harvey J. Tompkins, director, psychiatry and neurology service, Department of Medicine and Surgery, Veterans Administration, Washington, D. C.; Gregory Zilboorg, New York, and Alfred C. Kinsey, director, Institute of Sex Research, Bloomington, Indiana. There will be a large number of technical exhibits. Dr. Appel will be the principal speaker at the dinner Feb. 25. There will be no charge for registration, and all interested professional personnel will be welcome. Information may be obtained from Dr. Ewin S. Chappell, Veterans Administration Hospital, North Little Rock, Ark.

MISCELLANEOUS

Positions Open in Food and Drug Administration.—The Food and Drug Administration of the U. S. Department of Health, Education, and Welfare is actively recruiting medical officers to work in Washington, D. C. The positions pay an entrance salary of \$7,040 to \$9,600 with increments. The duties of the positions provide for medical decisions relating to food, drugs, devices, and cosmetics, as well as participation in the medical phases of legal actions against violative products. For further information write to Dr. Irvin Kerlan, Acting Medical Director, Food and Drug Administration, Washington 25, D. C. Interested physicians should also file for Medical Officer Examination, Examining Circular EC-24, issued April 5, 1950, with the U. S. Civil Service Commission, Washington 25, D. C., stating special preference for a position with the Food and Drug Administration.

Twenty-five Billion-Volt Accelerator to Be Built at Brookhaven.—The U. S. Atomic Energy Commission has approved the construction at Brookhaven National Laboratory of an ultra-high-energy particle accelerator for nuclear research. The new machine, an alternating gradient synchrotron, will be designed to produce beams of protons of energies ranging up to 25 billion electron volts. The cost of design and construction of the new accelerator is estimated at 20 million dollars. Design work will start in the near future, and the machine is expected to be completed in five to six years. Once in operation, it will be available to scientists wishing to collaborate in Brookhaven research programs or to carry out independent programs. Particle accelerators have played an important role in the advancement of nuclear science. The energy of the particle beams produced by accelerators bears a direct relationship to the nuclear phenomena that can be studied. As higher energy levels have been attained in laboratory machines, new subnuclear particles have been discovered and new nuclear phenomena observed. The most powerful accelerator now in operation is the Brookhaven Cosmotron, which has accelerated protons to energies of 2.3 billion electron volts. The Bevatron, under construction at the University of California Radiation Laboratory at Berkeley, is expected to accelerate particles into the 5 to 7 billion electron volt range. By providing particles with energies as high as 25 billion electron volts, the Brookhaven alternating gradient synchrotron is expected to contribute important new knowledge of the fundamental nature of matter. Brookhaven National Laboratory, a research center equipped with facilities that no single university could afford, is operated for the AEC by Associated Universities, Inc., a corporation formed by nine northeastern universities: Columbia, Cornell, Harvard, Johns Hopkins, Massachusetts Institute of Technology, Princeton, University of Pennsylvania, University of Rochester, and Yale.

FOREIGN LETTERS

ITALY

Bronchial Adenoma.—At a meeting of the medicosurgical society of the Romagna region, April 20, 1953, Professor D'Arcangelo and his co-workers reported on two patients with bronchial adenoma, both of whom recovered completely. In recent years many contributions have been added to the medical literature on this disease, which in the past was often confused with bronchial carcinoma or inflammatory pulmonary disease. Bronchial adenoma is a neoplasm that originates from the mucous glands of the main bronchi. Although histologically it simulates one type of bronchial carcinoma, it is never complicated by regional and general metastases. Although it may be considered benign from the histological point of view, it should be considered malignant from the clinical point of view. It causes bronchial stenosis, obstructive emphysema, atelectasis, purulent bronchiectasis, pleural reactions, and eventually death from pneumonitis.

The prognosis of bronchial adenoma has greatly improved in recent years, and most patients can be cured by surgical removal of the neoplasm. These good results were made possible by the wider use of bronchoscopy, which is the main means of diagnosis, and by progress in thoracic surgery after the introduction of curare and intratracheal intubation anesthesia. The first of the two patients treated by Professor D'Arcangelo and his co-workers was a young woman who from 1947 to 1951 had recurring episodes of inflammation in the lower lobe of her right lung that consisted mainly of bronchiectatic cavities. In the last year the patient was continuously ill, had a temperature of 100.4 F to 102.2 F, and raised 400 to 600 cc. of mucopurulent sputum every day. Bronchoscopy revealed a nodule, the size of a cherry, which was obstructing the bronchus to the lower lobe and which histologically was found to have all the characteristics of an adenoma. The lower lobe of the right lung was removed and the patient made an uneventful recovery.

The second patient was a 40-year-old man who during the first months of 1950 had episodes of subacute inflammation in the right lung and pleura that became more accentuated until they culminated in atelectasis of the middle lobe. A bronchial carcinoma was suspected, and bronchoscopy was performed. It revealed a swelling, the size of a cherry, in the right lower bronchus at its bifurcation with the middle bronchus. This swelling almost entirely occluded the bronchial lumen. Intra-bronchial diathermy was given, the neoplasm was entirely destroyed, and the patient's symptoms disappeared completely. Bronchoscopic reexaminations have failed to reveal any evidence of recurrence.

The speakers concluded that bronchial adenoma should be suspected in patients with chronic respiratory inflammation and signs of atelectasis or obstructive emphysema. It is wise in such cases to perform a bronchoscopy.

Research on Ballistocardiograms.—Drs. Sibilla and Foianini reported the results of their studies on the basal factor in the genesis of the ballistocardiogram before the Society of Cardiology in Rome on April 29, 1953. They produced stenosis or occlusion of the large vessels at various points in dogs and then registered the effects of these on the ballistocardiogram. They found that, as a rule, occlusion of the superior vena cava obliterated the diastolic waves and that stenosis or occlusion of the pulmonary artery caused accentuation of the diastolic waves. Conditions that diminish the cardiac output, such as aortic and pulmonary stenosis, are accompanied by a decrease in the amplitude of the systolic waves. Pulmonary stenosis is accompanied by an ample K wave. Aortic stenosis is accompanied by a diminution of the amplitude or disappearance of the I wave. Stenosis of the aorta at various points, from the isthmus to above the aortic bifurcation, is accompanied by

notching of the J peak or the JK segment and by disappearance of the K wave. Stenosis or occlusion of the aorta at the bifurcation does not cause the K wave to disappear, probably because of an increased aortic deceleration, as is observed in arterial hypertension.

These experimental findings do not necessarily apply to human beings. In fact, when aortic or pulmonary stenosis is present in human beings, hypertrophy, collateral circulation, and systems of adaptation that are not found in animals are also present. In abrupt occlusions, however, ballistocardiographic effects may be produced in men that are similar to those produced in animals. There are also suggestive analogies in stenosis of the aortic isthmus.

LONDON

Medicolegal Aspects of Spinal Anesthesia.—An interesting medicolegal case has just been decided in the courts. On the same day in 1947 two patients, aged 51 and 62, respectively, were given a spinal anesthetic (dibucaine [Nupercaine]) for a minor operation by the same anesthetist in the same hospital. In both permanent paraplegia developed, and they sued the Minister of Health, the anesthetist, and the manufacturers of the anesthetic for damages. At an early stage of the trial the manufacturers were dismissed from the action as having no liability. The contention of the plaintiffs was that the paraplegia was due to phenol that had percolated through the ampuls into the dibucaine. The ampuls had been stored in a 1:40 phenol solution colored with Bordeaux B, after temporary immersion in a 1:20 solution. The judge accepted the expert evidence that phenol can find its way into an ampul stored in a solution through "invisible cracks" or "molecular flaws" in the glass. This was a possibility to which Prof. R. R. Macintosh had drawn attention in 1951, but the risk was not realized in 1947 when the plaintiffs received their spinal anesthesia. The judge ruled out the possibility of the anesthetist having failed to notice a visible crack in the ampuls before using them. There was a clash of expert evidence at the trial, which lasted 11 days. Both Sir Francis Walsh, consulting physician to University College Hospital, and Dr. Macdonald Critchley, senior neurologist at King's College Hospital, expressed the opinion that the paraplegia could not be due to phenol and considered it to be due to the spinal anesthetic. Prof. R. R. Macintosh of Oxford, on the other hand, was of the opinion that the paraplegia was due to phenol. As the *Pharmaceutical Journal* points out, this case raises the question of how such ampuls should be stored. In his evidence at the trial, Professor Macintosh said the best method of sterilizing ampuls was by autoclaving.

British Orthopaedic Association.—At the annual meeting of the British Orthopaedic Association in Birmingham in October, in a discussion on replacement arthroplasty in elderly patients with fracture of the neck of the femur, O. J. Vaughan-Jackson reported that 32 of 34 patients in his series tolerated the operation well and one died. Fracture of the prosthesis occurred in four patients. He considered that use of metal in place of plastic would probably solve the problem. G. N. Golden, C. C. M. Murray, and A. H. Ord reported good results in 70% and satisfactory results in 15%. K. H. Pridie, on the other hand, considered that Judet arthroplasty should be reserved for patients in whom nailing had failed. In those treated by nailing, the results were satisfactory in 57%. Avascular necrosis was inevitable in 11%, but this was balanced by a 12% incidence of fractured acrylic prosthesis.

Strongly opposing views were expressed in a discussion of the causes of coccydynia. H. J. Richards, on the basis of an analysis of 102 cases, contended that in many cases coccydynia was caused by a central prolapse of one of the lower lumbar intervertebral disks. Almost half his patients had low back pain or sciatica initially; in almost all the rest these symptoms

developed later. K. I. Nissen denied this hypothesis. In his experience, repeated manipulation of the coccyx usually relieved the condition, though in 5 to 10% excision might be necessary.

A discussion on isoniazid in skeletal tuberculosis also revealed a difference of opinion. On the basis of his experience in 20 cases, mainly of tuberculosis of the spine, hip, and knee, treated for six months, A. G. Quinlan concluded that isoniazid caused a marked improvement in the patient's general condition but no dramatic effect on the tuberculous lesion. M. C. Wilkinson had seen little improvement in the synovial membrane after two months of treatment with isoniazid, and he preferred to combine antibiotic therapy with excision of the synovial membrane. A more optimistic outlook was that of M. B. Devas, who had treated 10 patients with a combination of streptomycin, *p*-aminosalicylic acid, and isoniazid for six months. In all of them the lesion was quiescent a year later.

Chemotherapy of Tuberculosis.—A report of the tuberculosis chemotherapy trials committee of the Medical Research Council (*Brit. Med. J.* 2:1005, 1953) compares the effects of streptomycin plus isoniazid and of *p*-aminosalicylic acid plus isoniazid in 391 patients with pulmonary tuberculosis after three months' treatment. The criteria for acceptance in the trial were: (1) tubercle bacilli present in smears of sputum taken within two weeks, or on culture derived from a specimen taken not more than two months previously; (2) tubercle bacilli resistant to neither streptomycin nor *p*-aminosalicylic acid; (3) no previous treatment with streptomycin, *p*-aminosalicylic acid, or isoniazid during the preceding three months; and (4) no concomitant pulmonary collapse therapy or pneumoperitoneum. The selected patients included those with acute rapidly progressive pulmonary tuberculosis believed to be of recent origin; those with other forms of pulmonary tuberculosis considered suitable for chemotherapy; and those with chronic forms of pulmonary tuberculosis expected to make only a limited response to streptomycin plus *p*-aminosalicylic acid.

The dosage schedules used were: (1) 1 gm. of streptomycin daily in one intramuscular injection, plus 200 mg. of isoniazid daily in two equal oral doses; (2) 1 gm. of streptomycin in one intramuscular injection, twice weekly, plus 200 mg. of isoniazid daily in two equal oral doses; (3) 20 gm. of *p*-aminosalicylic acid (sodium salt) in four equal oral doses, plus 200 mg. of isoniazid daily in two equal oral doses; and (4) 10 gm. of *p*-aminosalicylic acid (sodium salt) plus 200 mg. of isoniazid daily in two equal oral doses.

There were two deaths (0.5%) during the period of treatment: one in the first treatment group from renal failure secondary to acute nephritis and one in the third group after three weeks of treatment. There were no toxic reactions to isoniazid, but treatment had to be stopped in five patients in the third group because of toxic reactions to *p*-aminosalicylic acid. At the end of three months the general condition had improved in 89% of the patients in group 1 and 88% of those in the group 3. The average gain in weight was 5.8 kg. for group 1 and 4.9 kg. for group 3. The temperature fell to normal in 79% of the febrile patients in group 1 and 85% of the febrile patients in group 3. In patients with a pretreatment sedimentation rate of 21 or more, the rate fell to 10 or less in 37% of those in group 1 compared with 46% of those in group 3. Grade 2+ or 3+ radiographic improvement was seen in 54% of group 1 and 42% of group 3. The proportion of patients bacteriologically negative, both on direct examination and on culture, at a single examination, was 65% for group 1 and 66% for group 3. Sensitivity tests showed that tubercle bacilli from groups 3 and 4 showed practically no development of resistance to isoniazid or *p*-aminosalicylic acid. In tubercle bacilli from group 1 development of streptomycin resistance was largely prevented, but the incidence of isoniazid resistance was noticeably greater in organisms from group 2 (from 8 to 21 patients) than in those from group 1 (from 2 to 18 patients).

The committee concluded that 20 gm. of *p*-aminosalicylic acid plus 200 mg. of isoniazid daily, used for three months, is very effective in pulmonary tuberculosis. It ranks with the most efficacious chemotherapeutic combination so far tested, namely, 1 gm. of streptomycin plus 20 gm. of *p*-aminosalicylic acid daily. Both drugs are administered orally.

LUXEMBOURG

International Congress of Legal and Occupational Medicine.—The 25th International Congress of Legal, Social, and Occupational Medicine of the French Language was held in Luxembourg in May, 1953, under the chairmanship of Dr. Molitor, Director of Public Health of Luxembourg. Muller discussed neuropathological disturbances following emotional shock and stated that the expert witness must show (1) the reality and importance of the emotional trauma, (2) proof of an emotional shock, (3) evidence of predisposition in the previous emotional status of the patient, (4) the reality of the alleged disturbances, and (5) the details of the manifestations of these disturbances. Other reports dealt with the effects of pain on the ion equilibrium of the blood, differentiation of fetal and adult blood stains, detection of semen stains by acid phosphatase, radiological differentiation of human and animal long bones, and determination of arsenic in the hair and its value in the diagnosis of arsenical poisoning. Mosinger, in a paper on occupational cancer, proposed the following preventive measures: (1) prohibition of industrial use of all carcinogenic products that act by contact, inhalation, or ingestion; (2) reduction to a minimum of all contact with carcinogenic products; and (3) promotion of research on the carcinogenic action of products used in industry and dissemination of the results.

NORWAY

The Changing Clientele of a Skin Hospital.—In November, 1953, the opening of the rebuilt and modernized skin department of the Rikshospital in Oslo was the occasion for a historical survey of this institution by its chief, Dr. Niels Danbolt, professor of dermatology at the University of Oslo. When the forerunner of the hospital was opened in 1817, one of its objects was the teaching of skin and venereal diseases for medical students. The 8 primitive buildings, which lacked even proper foundations, were supposed to house about 25 patients, but the demands for admission were so great that up to 102 had to be housed at the same time. In spite of the miserable conditions under which these patients lived, some of them survived to "enjoy" the hospitality of this institution for up to 10 years. In 1844, again in 1854, and again in 1883 the hospital changed its site, and after the last change it had 72 beds. In 1889 the hospital was put in charge of Prof. Caesar Boeck whose name is immortalized in connection with sarcoid disease, hitherto taken or mistaken for tuberculosis. In Boeck's time also, the patients suffered, for the most part from venereal disease, and Boeck's careful study between 1890 and 1910 of about 2,000 patients with syphilis came to enjoy an international reputation because of its masterly analysis of the morbidity and mortality of this disease. As late as 1900 about two-thirds of the patients suffered from venereal disease, and only 10 or 15 years ago these patients still made up about one-third of the total.

Since Professor Danbolt became chief, the tendency for venereal disease to disappear from the skin hospital's clientele has continued, and, as he has recently pointed out, "The need for hospital beds for venereal cases is thus now exceedingly modest." The new building just opened provides inpatient accommodation for 87 patients and improved facilities for outpatient activities. Laboratories are provided for the study of the disturbances of the peripheral circulation, of importance to the treatment of varicose ulcers and allied conditions. Other laboratories are now available for the study of the allergic diseases, including eczema and fungoid diseases. A lecture hall is also provided for the benefit of students and nurses. The dwindling number of inpatients suffering from venereal disease reflects not only their growing rarity but also their amenability to outpatient treatment, thanks to recent advances in chemotherapy. On the other hand, growing demands are being made on the hospital's accommodation for the treatment of eczema which is constantly growing in importance as an industrial disease.

CORRESPONDENCE

ALTERNATING PRESSURE PAD

To the Editor:—Further experience with the alternating pressure pad since our initial report (*J. A. M. A.* 138:583 [Oct. 23] 1948) has convinced the professional and nursing staffs of various hospitals of its value in the prevention and treatment of decubitus ulcers (bedsores). For the past five years at the Cleveland Clinic Hospital, the pad has been used routinely for all patients admitted with decubitus ulcers as well as for those who are considered candidates for them. The latter group includes paralyzed, comatose, and severely debilitated patients. It is used also for those who find turning painful and for certain others who are immobilized by continuous traction or casts. It has proved a real aid in the proper nursing of these patients. In analyzing our experiences we have found that approximately 1 of every 25 patients admitted has been treated on the alternating pressure pad.

The pad is, in effect, a pneumatic massaging mattress that is placed on top of the ordinary bed mattress, as explained previously (*Mod. Hosp.* 71:72 [Nov.] 1948). It is made by Air-Mass, Inc., 12720 Lake Shore Blvd., Cleveland, of a plastic, waterproof material with parallel rows of air cells running across its width. Alternate series of these air cells are filled and emptied approximately every three minutes by means of a small electric pump that operates quietly 24 hours a day. The pressure in the inflated series of air cells is sufficient to support the patient's weight while the alternate series of cells is deflated. Viewed from beneath, the patient's skin can be seen to blanch and flush alternately as the air cells inflate and deflate every three minutes. The changes in pressure are gradual so that the patient is unaware of movement. The pad is placed on the bed mattress, and, in order not to lessen its effect, it is covered by only a single bed sheet.

Bedsores are gangrene of the skin caused by interference with circulation from pressure of the mattress on bony prominences. In their prevention and treatment, there is no substitute for good nursing care. The nurse's responsibility is to take time to (1) turn the patient frequently, (2) massage the threatened areas, (3) keep the bed dry, and (4) cleanse the ulcers. The use of the alternating pressure pad for patients predisposed to decubitus ulcers has made it possible to keep the skin healthy with the expenditure of half as much nursing time as was previously necessary. The pad has made possible more rapid healing of decubitus ulcers in patients admitted with them.

MISUSE OF WORDS IN SCIENTIFIC LITERATURE

To the Editor:—In scientific writing one enjoys the availability of words that express meaning and shades of meaning more exactly than in any other class of authorship. On the other hand, the very existence of such refinement of vocabulary carries a responsibility for the author to choose his words carefully in order that his exact intent of meaning is conveyed to the reader. Recent medical literature provides several examples of the misuse of the words toxicity, side-action, and idiosyncrasy. Such a misuse is unfortunate, particularly in the reporting of actions of new drugs, since an improper connotation is invariably conveyed when the wrong word is used. None of these words is synonymous with the others, and the use of toxicity and side-action is particularly confused in recent writing.

Toxicity is intended to express the quality of being toxic; toxic, in turn, is synonymous with poisonous. A poison is a substance that either destroys life or seriously impairs the function of one or more of the organs of the body. A side-action is not a toxic action nor is it evidence of idiosyncrasy. Most, if not all, drugs have more than one action, and side-actions of a drug are standard physiological or pharmacological activities on organs or tissues that are not primarily concerned in therapy. They may be illustrated by the activity of morphine in causing smooth muscle spasm when the drug is administered for relief of pain or by atropine in causing xerostomia when it is given to relieve smooth muscle spasm. Idiosyncrasy means an activity of a drug in a particular patient that is not seen in the vast majority of patients. It is defined as a peculiarity of constitution in that particular patient; a peculiarity that makes him react to the drug differently from most patients. Idiosyncrasies obviously occur relatively infrequently and may be illustrated again by morphine and the excitation resulting in a small percentage of patients after its administration. The correct use of these terms will avoid possible misinterpretation of an author's intent of meaning and enable the reader to obtain an accurate understanding of the writer's thought.

CORRECTIVE SURGICAL PLANING OF THE SKIN

To the Editor:—The paper by Kurtin (*Corrective Surgical Planing of Skin*, *A. M. A. Arch. Dermat. & Syph.* 58:389-397 [Oct.] 1953) elicits some comments. Credit should be given to Dr. Kurtin for having reintroduced a method that has certain usefulness, but that has been known for over 30 years. It was Kromayer ("Die Behandlung der kosmetischen Hautleiden unter besonderer Berücksichtigung der physikalischen Heilmethoden und der narbenlosen Operationsweisen," Leipzig, Georg Thieme, 1929, p. 15) who described this method that consists of freezing the skin with ethyl chloride and the subsequent use of various sizes of dental burrs mounted on a motor-driven flexible cord. This method is known to most Europeans (Volk, R., and Winter, F.: "Lexikon der kosmetischen Proxix," Berlin, Springer-Verlag, 1936, p. 545) and to a good many American dermatologists. Its usefulness was proved in the treatment of keloids, pigmented nevi, freckles, lentigines, tattoos, Berlocque dermatitis, and superficial pitted scars. Kromayer also recommended this method in the treatment of the hyperpigmented borders of vitiligo.

I have had extensive experience with this method, and I am convinced that the use of dental burrs has a definite advantage over the brush or sandpaper method. While planing can be achieved with wire brushes and sandpaper, the small size of the burrs is more advantageous and permits greater precision in the treatment of tiny areas. Furthermore, it is far easier to control the depth of abrasion with the firm burrs than with the brushes or sandpaper.

ALLERGIC DISEASE IN THE NEWBORN

To the Editor:—In the Oct. 17, 1953, issue of THE JOURNAL there appeared an article called "Prophylaxis of Allergic Disease in the Newborn." It was inferred that allergic conditions could be minimized if various foods were restricted from the mother's diet during pregnancy. It was also advocated that the newborn be given Mull-Soy, a soybean milk formula, instead of milk. Both of these suggestions need confirmation, for during the past 15 years I have observed 59 pairs of monozygous twins, and, of these, 52 sets had only one twin presenting an allergy. The study of twins gives a controlled study rarely duplicated naturally or clinically, so if only 50% present an allergy, how can any deduction be made statistically as has been offered in the article mentioned? Constructively, I believe that if mothers could be more successful in feeding breast milk and physicians less eager to give foods that infants are not ready to digest, perhaps allergy would be minimized.

THE LEISURE CORNER

TOOLING LEATHER AS A HOBBY

The desire to create and the capacity to admire beautiful objects is strongly ingrained in most of us. To enjoy fully the exciting experience of creation in the field of tooling leather, i. e., the impression and shaping of leather, the craftsman-hobbyist obviously requires knowledge of the medium in which he has chosen to work. Interest in tooling leather—or, for that matter, in any form of handicraft—is enhanced by the type of decoration adorning the object of one's artistic expression. When a decoration is original in design, interest becomes intensified. Familiarity with material and tools is, of course, important. A hobbyist should become reasonably well acquainted with various leathers, their adaptability to a variety of products, and their utilitarian functions.

Cowhide and calfskin constitute the main tooling leathers. Other types of leather can also be used for stamping, but, by and large, their appropriateness for the purpose of satisfying the requirements of a hobby is limited. Preference for cowhide over calfskin, or vice versa, depends largely on the finished article and its utilitarian function. If one were to select leather for a brief case, heavy cowhide would be the leather of choice, particularly since it is capable of withstanding hard wear. On the other hand, calfskin possesses the

softness and pliability demanded in ladies' handbags and men's wallets (see figure). In general, a leather supply house can readily furnish to the hobbyist scraps of leather that he can test for depth of impression and specific suitability. Once a decision has been reached, he can proceed with the purchase of leather that will meet his purposes.

A leather surface can be covered by any one of a number of different designs merely by tooling the design on the finished side of the material. Few tools are required. Modeling tools are usually shaped to establish specific impressions. One such tool is a combination tracer and beveler. The tracer end is used to transfer the outline of a design from paper to leather; it is also used to deepen the impression so that it is not lost when subsequent wetting of the leather takes place. The beveled end is employed for shaping, rounding off parts of a design, or separating design and background. A background tool has the shape of a spatula. Each end differs in size in order to accommodate various areas. Some modeling tools contain two ballpoint ends. For straight line tracing and deepening, use of a straight metal edge is most satisfactory. The background of a hand-tooled leather article is usually devoid of decoration, since its presence would detract from the main design. In the event a decorated background is contemplated, it can readily be produced by means of background stamps. These can be purchased either in various designs or they can be made by the hobbyist himself in a desirable form from pieces of mild steel. For physicians who wish to experiment with tools to suit individual fancy, dentists' instruments offer a challenge to ingenuity. Home-shaped modelers are quite adequate for production of numerous lines and shapes, differing from purchased tools in that only one end is shaped.

Before a design is transferred to leather, it should be carefully drawn on thin, medium-hard paper. Leather should first be moistened to receive and retain an impression. During the preparatory stage, the unfinished side is sponged sufficiently to indicate water stain on the finished side. Accumulation of moisture in excessive amounts affects the impression and should be avoided. After being properly placed, the paper is attached to the leather by means of clips. Damp leather is unduly sensitive to pressure, and paper clips leave a mark accordingly. However, since it is generally fastened to a marginal site outside of the design itself, the impression produced by a clip rarely damages either design or leather. As soon as paper and leather are attached, the tracer is used to follow the design on paper and to transfer it to leather. The paper pattern is then removed, the remainder of the tooling process consisting of direct contact between modeler and leather. As he proceeds to his goal, a certain degree of originality may be exercised by the craftsman-hobbyist. When modeling a floral pattern, it may be desirable, for example, to tool away from the form in one case or to shape the form in another. Then there are those hobbyists who wish to employ both techniques. It is possible, to a certain extent, to achieve the effect of etching and embossing as well as cutting and piercing.

Some working in the tooling leather medium will be interested in portraits on leather. For this purpose an additional instrument is required—the familiar scalpel. An incision is made and the finished surface separated from the rest of the leather thickness so as to form a pocket. The pockets are then stuffed with cotton to raise the surface, and the leather is glued at the site of incision. This results in a raised cheekbone, a shaped nose, rounded eyes, or any other anatomic features.

Despite a well established step-by-step procedure for tooling leather, the hobbyist is not restricted to a single style or technique. Leather furnishes luxurious opportunity for innovation to creative minds and supple imaginations.

BUSINESS PRACTICE

The following material is based on a public relations manual issued by the Public Relations Department of the American Medical Association.—ED.

EXPLAINING AND COLLECTING MEDICAL FEES.

Because many doctors—and patients—are reluctant to broach the subject of fees, the American Medical Association now sells an attractive office plaque that encourages fee discussions with this message: "To All My Patients—I invite you to discuss frankly with me any questions regarding my services or my fees. The best medical service is based on a friendly, mutual understanding between doctor and patient." A physician should be prepared to give his patient an estimate of the cost of his care. The physician who thinks he soothes his patient by saying, "Don't you worry about money; just concentrate on getting well," is side-stepping his responsibility. Some physicians hand patients an estimate of medical expenses before hospitalization. Explanations of medical costs should extend beyond the doctor's own charges. For example, if a patient is to undergo an operation, the physician should explain the surgeon's, anesthesiologist's, and radiologist's charges; the laboratory fees; and home, hospital, and office call charges as well as the approximate hospital bill, which may include an operating room fee, charges for medicines and dressings, laboratory fees, and the cost of blood transfusions. The importance of calling in another physician for consultation should be explained to patients, and it should be made clear that there will be a separate fee for the consulting physician. People are inclined to blame doctors for all medical costs, even hospital charges. The doctor can avoid misunderstanding by giving the patient an idea of what the whole medical procedure will cost him.

When it comes to collecting medical bills, the following steps are recommended:

1. Send itemized bills regularly.
2. After three monthly statements have been sent and no remittance received, send a reminder note in the fourth month signed either by the doctor's secretary or the doctor himself:

Dear:

We thought perhaps you had overlooked this statement which has been charged against your account since

3. If there is no reply to the above reminder, a personal letter from the doctor should be sent in the fifth month.

Dear:

Since you have not been to see me for some time, I trust that you and your family are all well. My bookkeeper tells me that your bill for \$35 has been on our books for several months. If you have questions about the charges or have some other reason for not making the payment, please come into the office and talk to me about it. We want to help you in any way that we can.

4. If no reply is forthcoming, the doctor should write a letter of this type in the sixth month:

Dear:

Last month I wrote you that your bill for \$35 has been on our books for six months. I thought perhaps we might help you. I was surprised that you did not answer my letter or come in to my office to talk to me about it. Won't you please get in touch with me soon so that we can settle this matter?

5. If a patient ignores this letter, too, he is obviously not acting in good faith. At this point the account may be turned over to an agency for collection and the following letter sent:

Dear:

We have sent you statements and reminders and written you several times in regard to your bill for \$35, which has been due for the past six months. Since we have not heard from you, we have no other course but to turn the account over to a collection agency. If we do not hear from you within the next 10 days, all further contacts in regard to this bill will be made by a representative of the agency.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Charitable Hospitals: Criteria of Tax Exemption Status.—This was a mandamus action to have the plaintiff's property declared exempt from taxation and removed from the tax rolls. The action was heard in the Supreme Court of Kansas.

The plaintiff, Atchison, Topeka and Santa Fe Hospital Association, alleged that it was incorporated as a non-profit corporation, without capital stock and that the property in question was owned by it and used and operated exclusively for charitable and benevolent hospital purposes. The Kansas constitution provides: "All property used exclusively for state, county, municipal, literary, educational, scientific, religious, benevolent and charitable purposes . . . shall be exempted from taxation." And the statutory provision on the same subject provides: "That the property described in this section, to the extent herein limited, shall be exempt from taxation: . . . All buildings and parts of buildings belonging to scientific, literary and benevolent associations, used exclusively for scientific, literary or benevolent purposes. . . ." The evidence showed that the hospital was operated by funds raised from dues of members, all employees of the Atchison, Topeka and Santa Fe Railroad, and by annual contributions from the railroad in the amount of seven per cent of the dues plus the

furnishing by the railroad of transportation, auditing, accounting, and other services at no cost to the hospital association. The hospital was not open to nonmembers except in cases of extreme emergency, however, and the defendant therefore contended that the hospital was an exclusive affair, comparable to an exclusive club, with the benefits accruing only to its closed membership. In a prior case the Supreme Court of Kansas held that a hospital that was owned and managed by a corporation organized for benevolent purposes, that paid no dividends, that devoted all its income to the care of sick or injured persons and to improving and extending its facilities for so doing, and that received and cared for patients without discrimination as to their race, color, or creed was a charity and its property was used exclusively for charitable purposes. The defendants conceded the force of this decision but pointed out that in the present case the hospital facilities were available only to railroad employees who are in good standing and not to the general public. They argued that this distinction took the case out from under the rule announced in the former decision.

Generally, said the Supreme Court, where the statute exempts institutions of purely public charity, an organization limiting its benefits to a restricted class is not exempt. A different rule ordinarily prevails, however, when the property rather than its owners is exempted from taxation if devoted to charitable purposes. Under the Kansas constitution it is the particular property that is exempt and its exemption depends on its use. Those states that hold that property used principally for the benefit only of persons in some way related to the members of a society, an artificial class as it is called, is nonexempt, do so generally for the reason that the law governing the case requires that the charity shall be a purely public charity. The various private charities that provide for any portion of the public, however, relieve the public and all taxpayers of a certain portion of the public burden and are thus a benefit to all; the numerous so-called private charities provide in the aggregate for as great a portion of the poor and dependent, which the state is under obligation to support, as do the so-called public charities. That the benefits of a home for the support of widows and orphans are confined to the members of a particular secret society does not deprive it of the character of a purely public charity within the meaning of a constitutional tax exemption. In the present case, the Supreme Court concluded, the property of the Atchison, Topeka and Santa Fe Hospital Association is not being used or operated in connection with the promotion of any other business. The property, both real and personal, of the association is, therefore, being used exclusively for charitable and benevolent purposes and hence is exempt from taxation pursuant to the provisions of the Kansas constitution. Accordingly, the Supreme Court entered judgment in favor of the plaintiff hospital association. *A. T. & S. F. Hospital Association v. State Commission of R. and T.*, 246 P. (2d) 299 (Kansas, 1952).

MEDICAL MOTION PICTURES

FILM LIBRARY HAS RECORD YEAR

A total of 2,273 films were lent to medical societies, medical schools, hospitals, and other scientific groups in 1953 according to Ralph P. Creer, Secretary, Committee on Medical Motion Pictures. This represents an increase of 185 over the previous year and is a 45% increase in the number of films distributed during 1951. This is in addition to the more than 100 A. M. A. films sent to medical societies and television stations for use on various television programs.

Prevention of Hypochromic Anemia in Infants.—Ferric iron as ferric ammonium citrate was given to 115 full-term infants and ferrous iron as ferrous sulfate was given to 37 full-term infants in order to determine the amount and form of iron needed for prevention of hypochromic anemia in infants in whom this disease continues to occur commonly in the latter half of the first year of life. In addition, seven immature or prematurely born infants were studied. The dose of iron given to the infants in their formulas from the 12th to the 52nd weeks of life or longer was 5 mg. daily at 3 months of age, increased to 10 mg. daily after 6 months of age. No instance of gastrointestinal irritation due to the iron was observed. Ferrous iron in the same dosage resulted in significantly higher hemoglobin values in well infants than did ferric iron. The small amounts of iron given daily were sufficient to maintain hemoglobin values at a constant level throughout the latter half of infancy in all full-term infants. Even in infants with severe upper respiratory infections pronounced anemia did not occur, but hemoglobin values were maintained above 10 mg. per 100 cc. Premature infants and infants of multiple birth may need more assistance in the prevention of anemia than is provided by these small daily quantities of iron. A small transfusion at 15 to 20 weeks of age was efficacious in restoring the hemoglobin value to near normal, after which 10 mg. of iron daily maintained the hemoglobin at normal levels. The authors' studies corroborated the findings of other workers that severe infectious illness in infancy is accompanied by significant decrease in the hemoglobin level. Mild infections, on the other hand, caused no significant decrease. The amount of iron storage at birth depends on the adequacy of the mother's diet, the length of gestation, and the watchfulness of the obstetrician that the umbilical cord is not clamped until all pulsations cease, so that the baby receives the maximum amount of blood possible. The infant born at term of a healthy well-fed mother will maintain a good hemoglobin level at least up to six months of age. If he receives some iron-containing foods daily after the fourth month of life, probably no other iron supplements will be necessary. An infant receiving only the iron of milk generally shows a slow decrease in hemoglobin level during the latter half of infancy, and, if his original iron store is poor, an iron deficiency anemia will occur in late infancy. In view

of the many variables involved in determining the iron available to the infant and the difficulty in evaluating each variable, the effect of a daily dosage of iron maintained at a level sufficiently low to be given in the formula was studied by the authors. The reported results showed that hypochromic anemia was prevented by these small daily amounts (5 to 10 mg.) of iron.

Anesthesia and Postoperative Personality.—A questionnaire survey was made of the parents of 612 children who underwent otolaryngological operations at the hospital of the University of Pennsylvania, correlating the preparation and induction of anesthesia with personality changes in these children. Results showed that 104 (17%) of the 612 children had personality changes that might be attributed in part to inadequate pre-anesthetic or anesthetic management. Thirty-two per cent of the changes reported were in the form of night cries or terrors, appearing either for the first time or becoming worse after hospitalization. Temper tantrums comprised 26% of the changes; fear phenomena constituted 23%; and the remainder (19%) pertained to bed-wetting. The younger the child the more likely is the development of personality changes. Unsatisfactory preanesthetic medication and induction of anesthesia is associated with a high incidence of personality changes in young children. Bed-wetting occurred five times more commonly after the use of vinyl ether (Vinethene), than after ethyl chloride, cyclopropane-nitrous oxide, or thiopental.

Invert Sugar in Insulin Coma Therapy.—Therapeutic insulin coma is at present terminated either by sugar in a gastric gavage or with intravenous injections of either 33.3 or 50% dextrose. It occurred to Mills and Moore that invert sugar, which is composed of equal parts of D-glucose and D-fructose, possesses certain characteristics that might make it advantageous for use in routine termination of insulin hypoglycemia or for emergency intravenous termination in those comas routinely terminated by gavage. The product is available commercially in 5% and 10% solutions. One-half of the patients subjected to insulin shock therapy at the Veterans Administration hospital in Hous-

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

ton, Texas, served as controls, their insulin coma being terminated by the rapid intravenous administration of 100 cc. of 50% dextrose. The remaining half of the patients was given 20% invert sugar by the same route and in the same amount. The study was continued for a month, during which a total of 89 comas were terminated with 100 cc. of 50% dextrose and 132 comas were terminated with 100 cc. of 20% invert sugar. It was found that there was no significant difference in the time required for clinical arousal from coma when invert sugar was used instead of dextrose, and this was also true when the electroencephalogram was used to determine arousal. Invert sugar was much less irritating to the tissues at the site of injection. Invert sugar gives a much more stable blood level immediately after injection than does dextrose, and it is believed that this fact may, by eliminating compensatory hypoglycemia, help to prevent secondary comas. The authors conclude that 20% invert sugar is at least as effective as 50% dextrose in returning to consciousness patients in insulin hypoglycemia. Insulin coma patients provide an excellent opportunity for further research in carbohydrate metabolism.

Causes of Cardiac Hypertrophy and Death.—A survey was made of 8,500 necropsies to determine the occurrence of death from uncomplicated coronary artery disease in both sexes up to the age of 70 years. Of these, 3,500 necropsies were analyzed from a hospital for chronic diseases, 4,550 from three general hospitals, and 450 from the Armed Forces Institute of Pathology. Cases with (1) blood pressure of 150 mm. Hg systolic and 100 mm. Hg diastolic or more, (2) heart weights of 400 gm. or more, (3) nephrosclerosis, and (4) histological evidence of generalized cardiac fiber hypertrophy not due to valvular disease or myocarditis were regarded as indicative of previous hypertension and were, therefore, excluded. At the hospital for chronic diseases the incidence of uncomplicated coronary artery disease was 0.65%. At the three general hospitals the proportion ranged from 7.95% to slightly more than 10%. The incidence of uncomplicated coronary artery disease might even be smaller if it were possible to determine the number of cases of hypertension with small hearts without nephrosclerosis or an adequate history of elevated blood pressure. Since nephrosclerosis is concomitant with hypertension, an attempt was made to answer the question as to whether coronary disease and cardiac infarction cause cardiac hypertrophy. Results of comparing the incidence of cardiac hypertrophy in cases of myocardial infarction, both with and without nephrosclerosis, indicated that nephrosclerosis is directly related to cardiac hypertrophy and that myocardial infarction is probably not causally related to cardiac hypertrophy. Analysis of 450 sudden deaths among young soldiers showed a high percentage of hypertension, especially if left ventricular or generalized cardiac hypertrophy was regarded as indicative of this condition. The incidence of uncomplicated coronary artery disease among these deaths was not large, when it is considered that the material was pooled from two world wars, Civilian Conservation Corps camps, and civilian government employees comprising millions of personnel. Death was frequently due to coronary insufficiency resulting from the rigors of military life. Uncomplicated coronary artery disease occurs in clinical cardiac practice, especially in men, but is not common as a cause of death in hospital practice in either sex. The idea that patients die on the way to the hospital is dispelled by its uncommon occurrence in the files of the coroner. In the absence of cardiac hypertrophy, coronary artery disease does not cause chronic congestive failure frequently. With the subsequent development of a collateral circulation there also may be freedom from coronary insufficiency.

Chemotherapy of Pulmonary Tuberculosis.—A comparative study of the effects of isoniazid combined with streptomycin and of isoniazid combined with *p*-aminosalicylic acid was carried out on 391 patients with pulmonary tuberculosis after three months' treatment in 50 hospitals. Of the 391 patients, 119 were given 1 gm. of streptomycin daily and 100 mg. of isoniazid twice daily; 100 patients received 1 gm. of streptomycin twice a week plus 100 mg. of isoniazid twice daily; 101 patients were given 5 gm. of the sodium salt of *p*-aminosalicylic acid four times daily plus 100 mg. of isoniazid twice daily; and the remaining 71 patients received 5 gm. of the sodium salt of *p*-aminosalicylic acid twice daily plus 100 mg. of isoniazid twice daily. Three groups of patients were studied. Group 1 included those with acute rapidly progressive disease of recent origin. Group 2 was comprised of those with other forms of pulmonary tuberculosis considered suitable for chemotherapy. Group 3 included those with chronic disease unlikely to respond to streptomycin combined with *p*-aminosalicylic acid. A full comparison of the four methods of treatment in all three groups of patients will be made when results for more patients are available. The present report is concerned with the principal comparison of therapeutic results obtained in patients in groups 1 and 2 treated with 1 gm. of streptomycin daily plus 200 mg. of isoniazid daily (called SH patients) with those treated with 20 gm. of *p*-aminosalicylic acid (sodium) daily plus 200 mg. of isoniazid daily (called 20 PH patients). The distribution of patients with severe and less severe illness was similar in the SH patients and in the 20 PH patients. After three months of treatment, the general condition had improved in 89% of the SH patients and in 88% of the 20 PH patients. The average gain in weight was 12.8 lb. (5.8 kg.) for the SH patients and 10.8 lb. (4.9 kg.) for the 20 PH patients. The temperature was restored to normal in 79% of febrile SH patients and 85% of febrile 20 PH patients. The erythrocyte sedimentation rate of 21 or more before treatment was reduced to 10 or less in 37% of SH patients, compared with 46% of 20 PH patients. Changes in radiographic appearances were independently assessed by a radiologist unaware of the treatment of any patient. Two plus or three plus improvement was observed in 54% of the SH patients and in 42% of the 20 PH patients. There were two radiographic deteriorations and one death on each treatment. None of the reported differences are statistically significant. The proportion of patients bacteriologically negative both on direct examination and on culture, at a single examination at three months was 65% for the SH patients and 66% for the 20 PH patients. Bacillary resistance to isoniazid was observed in 2 of 39 SH patients with positive cultures tested at three months, compared with none in 29 similar 20 PH patients. Bacillary resistance to streptomycin was observed in 1 of 38 SH patients with positive cultures and to *p*-aminosalicylic acid in 1 to 28 similar 20 PH patients. It is concluded, judging solely from the results at three months, that *p*-aminosalicylic acid sodium in doses of 20 gm. daily combined with isoniazid in doses of 200 mg. daily is a very effective combination of drugs, both clinically and bacteriologically; it ranks with the most efficacious treatments so far studied, namely streptomycin in doses of 1 gm. daily plus isoniazid in doses of 200 mg. daily and streptomycin in doses of 1 gm. daily plus *p*-aminosalicylic acid sodium in doses of 20 gm. daily.

Hexamethonium Bromide and Cerebral Circulation.—The cerebral blood flow was estimated by a modification of the nitrous oxide method in six patients between the ages of 32 and 62 with arterial hypertension before and after administration of hexamethonium bromide. The mean arterial blood pressure fell by an average of 30%, but no significant change occurred in mean cerebral blood flow. The rate of cerebral oxygen utilization was measured in four of the six patients and showed no essential alteration. These findings imply that cerebral nutrition and metabolism will not ordinarily be impaired by the treatment of hypertensive patients with hexamethonium bromide, since cerebral vascular relaxation to a degree sufficient to maintain adequate cerebral blood flow and oxygen consumption accompanies reduction of blood pressure of the order obtained in the authors' patients. The possibility of an increased likelihood of cerebral thrombosis in patients in whom arterial disease favors the occurrence of such a complication cannot be considered to be eliminated by the present findings.

Medial Thinning in Atheroma.—Accounts of the histology of atheroma pay little attention to the media; it is usually passed over with the statement that it may show thinning, which is said to be a pressure atrophy due to compression by the overlying plaque. During a recent study of other aspects of aortic atheroma, Crawford and Levene noticed that even quite trivial plaques were associated with medial thinning. They feel that the idea that it is a pressure atrophy is not founded. They measured the amount of medial thinning at atheromatous areas from aortas and iliac arteries fixed (a) in the usual way and (b) in the distended state at arterial pressure. All but one of 134 plaques from undistended vessels and all 76 plaques from vessels fixed in distention showed definite medial thinning. In the distended vessels, the ordinary atheromatous plaques do not project into the lumen but lie in a depression in the media that may bulge outward. Only advanced plaques with recent thrombotic accretions project noticeably into the lumen—the familiar intimal bulge is a post mortem artefact. Physical considerations rule out pressure as the cause of the medial thinning, and the occurrence of outward bulging of the media indicates that something more than a disuse atrophy is concerned. The early and constant appearance of the medial thinning supports the contention that it is not a secondary result of the atheromatous process but an essential part of it, and the lesion as a whole is comparable to a shallow aneurysm partially or completely filled by the plaque of intimal thickening.

Spread of Prostatic Carcinoma to Bones.—Secondary deposits from malignant prostatic tumors are commonly found in the bones of the pelvis, the femurs, and the vertebral bodies, but there was no adequate explanation of this distribution of metastases until Batson in 1940 suggested that the vertebral venous system offered a possible path of spread. The aim of the studies described here was to confirm the fact that direct vascular communications exist between the prostate and the pelvic and spinal bones. Injections of a commercial barium suspension (Micropaque) of standard particle size (0.2 μ) were made into the deep dorsal vein of the penis of 15 adult male cadavers in the age range 43 to 75 years, using a pressure of

60 to 100 mm. Hg. About half a liter of suspension was used in each case. The bodies were then radiographed. The prostate, and in some cases the thoracic and lumbar vertebrae, the femurs, and the pelvic and other bones were then removed, fixed in neutral buffered formaldehyde (Formalin), cut into thin slices (2 to 4 mm.), filmed again with a crystallographic tube, and then examined histologically. A direct communication between the prostatic veins, the vertebral venous system, and the veins of the pelvic bones was confirmed by these methods. The distribution of bone metastases of prostatic carcinoma may be explained by spread along these veins. Other possible paths by which prostatic carcinoma may reach the skeleton are briefly discussed.

Risks of Tonsillectomy.—According to McKenzie the chance of serious infection after tonsillectomy has nearly disappeared. Before the discovery of penicillin, otitis media was quite common after tonsillectomy in children, and many surgeons can remember a subsequent death from meningitis. Serious infection after tonsillectomy is now rare. The anesthetic risk also is less now, if the anesthetist is a specialist. The expert keep their patients under too light anesthesia. The author feels that the best anesthetic for tonsillectomy is thiopental (Thiopentone) sodium given intravenously combined with an intratracheal tube that delivers oxygen. Hemorrhage at operation is likely if there has been a recent infection, e. g., a sore throat and a cold, or if there has been a peritonsillar cellulitis at any time, because of the resulting peritonsillar fibrosis. Discussing the risks during recovery from the anesthetic, the author says that the patient should be on his side with his face visible, and both hands should be in front of the chest. If the patient is not on his side and the airway is not free, there is a risk of sudden death from asphyxia by the tongue falling back. If active bleeding is noticed just before complete consciousness returns, the patient should be brought back to the operating room at once. If a second operation has to be undertaken for hemorrhage, the best time is before recovery from the first operation. The correct treatment for hemorrhage within 24 hours is to tie the blood vessel while the patient is under general anesthesia. The only exception is in the case of a well-disciplined adult who may allow local pressure of a swab if he has been given a small injection of morphine first. The bleeding may sometimes come from the nasopharynx. If it has been serious, the blood vessel should be tied and a gauze pack left in the nasopharynx for 24 hours. Hemorrhage after the first 24 hours after operation is seldom serious; the usual cause is the separation of the slough from the tonsillar fossa. Since this may not take place for 10 or 12 days, secondary hemorrhage may be delayed for that length of time. The author also points out that a swab can easily be left in the upper part of the tonsillar fossa. To avoid this, he touches both fossae and the nasopharynx and then looks into them with the help of a head light.

The Insulin Myth.—Bourne shows that there is no sound basis for the opinion that insulin coma therapy counteracts the schizophrenic process in some specific manner and that its therapeutic effects are greatly superior to those obtainable by electroconvulsive therapy. The summary of a series of 376 schizophrenic soldiers, 186 of whom he followed up by letter

two years later, suggests that acute schizophrenic illnesses are becoming more benign. Of the 376, 84% were discharged, nearly all within nine months, as recovered or improved sufficiently not to need further hospital care, and the follow-up indicated no strikingly extensive or rapid relapse rate. For 156 patients treated with electroconvulsive therapy, the corresponding figure was 83%; of 15 treated with insulin coma, with or without electroconvulsive therapy, 9 resumed ordinary life, while for 205 untreated patients the figure was 88%. It should be added that in both treated groups a substantial number of psychoses subsided long after the treatment could have been responsible. Among the fallacies arising from the nature of insulin therapy the author mentions that the mode of selection of patients for insulin coma is biased. Reports are uniform that the best results are obtained where, without any treatment, the prognosis would be most favorable; so cases selected for insulin treatment are only those considered most likely to benefit—that is to say, to get better anyway. It is no wonder that an "impression" is so often met that the quality of remission after insulin is superior. It would be surprising if it were otherwise. Practically all reports comparing insulin favorably with electroconvulsive therapy omit how patients were chosen for either treatment; but they contain details from which this bias can be strongly suspected. The evidence for the value of insulin treatment is unconvincing.

Minerva Ginecologica, Turin

Amniotic Fluid Pulmonary Embolism.—Pulmonary embolism caused by amniotic fluid is characterized by sudden shock during or immediately after a difficult labor. Only 43 cases of the disease (all fatal) have been reported since Steiner and Lushbaugh first described it in 1941. Macroscopic examination reveals pulmonary edema and microscopic examination a diffuse embolism in the pulmonary arterioles and capillaries in which amniotic fluid elements, such as meconium mucus, epithelial squamæ, and vernix caseosa, are present. The pathogenesis of the disease has not been clearly established, although it is known that the amniotic fluid enters the maternal circulation through the placental barrier because of an oversize fetus, or strong and tetanoid contractions of the uterus with excessive compression of the amniotic fluid, or laceration of the membranes. The mechanism of action of the amniotic fluid after its penetration into the maternal vascular system is still obscure. Some authors attribute great importance to the anaphylactoid reaction that follows the embolism, others to alteration of the blood coagulation mechanism because of the thromboplastin-like activity of the amniotic fluid, and others to anaphylaxis that follows a primary sensitization of the mother to the amniotic fluid. The author performed a series of experiments on rabbits and guinea pigs. Amniotic fluid alone even in massive doses and high concentrations did not cause diffuse pulmonary embolism and death in the animals. On the other hand, meconium alone even in low concentrations caused massive pulmonary embolism and death. A comparative experimental study revealed that the mechanism of action of meconium mucus embolism is parallel to that of fat embolism. The shock that occurs in the course of this syndrome is secondary to the embolism. The alterations induced on the blood coagulation mechanism by the thromboplastin-like activity of the amniotic fluid may aggravate the patient's condition. It may be that this embolism could be overcome if it occurred in patients in whom a difficult labor and a difficult puerperium had not impaired the circulation and the heart. The author states that the appropriate term for this disease should be "meconium embolism" rather than amniotic fluid embolism. Even more appropriate is the term Steiner and Lushbaugh's disease.

BOOK REVIEWS

Living with a Disability. By Howard A. Rusk, M.D., and Eugene J. Taylor. In collaboration with Muriel Zimmerman, O.T.R., and Julia Judson, M.S., Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center. Cloth. \$3.50. Pp. 207, with 281 illustrations. Blakiston Company (division of Doubleday & Company, Inc.), Garden City, New York; 575 Madison Ave., New York 22, 1953.

For several years the group of workers at the Institute of Physical Medicine and Rehabilitation of the New York University-Bellevue Medical Center has been collecting descriptions of "self-help devices and gadgets that might aid disabled persons in the performance of the daily activities of life and work." These descriptions were then included in a series of publications that were made available to professional workers. This well-printed and profusely illustrated textbook includes these descriptions in one convenient volume, which can be used as a guide by rehabilitation workers or by the handicapped persons themselves. A major objective in treating any handicapped person is to assist him to become independent and self-sufficient, and the devices described in this book help to achieve this objective.

The descriptions are prepared in a style that is readily understandable, even for nonprofessional persons. This is the first textbook to provide detailed descriptions and sources of supply of so many modern aids toward rehabilitation of handicapped persons. It is divided into sections dealing with (1) taking advice, (2) getting three meals a day, (3) looking one's best, (4) keeping up appearances, (5) doing things differently, (6) getting around indoors and out, (7) conquest of the kitchen, (8) living with one's home, and (9) planning time to relax. Among the interesting devices described and pictured are special eating utensils that can be used by persons with severe weakness or deformity of the upper extremities; devices to aid handicapped persons in dressing themselves, in ambulation, and in attending to their toilet; apparatus to assist in writing, typing, telephoning, page turning, and reading; and modifications of wheel chairs, walkers, crutches, canes, supports, automobile controls, kitchens, kitchen and household equipment, and recreational equipment to permit their use by handicapped persons. This interesting book should be extremely useful in helping many disabled persons to self-sufficiency and independence. It is recommended to all physicians and health workers who deal with patients having serious physical disabilities.

Diseases of Women. By Robert James Crossen, A.B., M.D., F.A.C.S., Assistant Professor of Clinical Gynecology and Obstetrics, Washington University School of Medicine, St. Louis. Tenth edition. Cloth. \$18.50. Pp. 935, with 990 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

The first edition of this book appeared in 1907 and the ninth in 1941. The present editor has carried on the work of his late father. Two chapters in the previous editions have been deleted and several new ones added, notably one by Willard Allan entitled "Endocrine Relations Concerned in the Ovarian Cycle" and one by A. N. Arneson entitled "Radiation Therapy." The chapter on anatomy and physiology occupies one-eighth of the entire book. In spite of the fact that the author emphasizes the importance of the psychosomatic aspects of gynecologic problems in the preface, the section devoted to psychosomatic aspects of gynecology occupies only three and a half pages. The words psychosomatic, psychogenic, and psychotherapy do, however, appear in the discussions of puberty, dysmenorrhea, dyspareunia, menopause, pruritus vulvae, and sterility. The author devotes five pages and many illustrations to vaginal pessaries. Many of the illustrations are borrowed from other sources, and most of these are instructive and definitely worth reproducing. It is, however, ques-

tionable whether, in such a textbook as this, it is proper to reproduce illustrations that were prepared by pharmaceutical companies for use in their advertisements. These are minor criticisms of a book that is well written, abundantly illustrated, well printed, and up to the standards of the previous editions. It contains a vast amount of information valuable for both students and practicing physicians, and it will undoubtedly continue to occupy a high position among textbooks of gynecology.

Clinical Disorders of the Heart Beat. By Samuel Bellet, M.D., Director, Division of Cardiology, Philadelphia General Hospital, Philadelphia. Cloth. \$8.50. Pp. 373, with 164 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

Dr. Bellet is eminently qualified to write a book on any phase of heart disease, and this text is based on his own wide experience. It is both a reference and a textbook, which aims to interest and inform the internist, general practitioner, and cardiologist. It ably attains this objective. It is comprehensive, accurate, easily readable, profusely illustrated, and has ample references. It should prove of greatest value to the general practitioner. The cardiologist might find much in it that seems elementary. As a reference book, it compares favorably with others published recently. The chapters on premature contractions and auricular flutter are particularly comprehensive and simply treated. This book should prove useful to physicians in general practice, the internist, the cardiologist, and to the intern or resident.

The Nursing Mother: A Guide to Successful Breast Feeding. By Frank Howard Richardson, M.D., F.A.C.P., F.A.A.P. Cloth. \$2.95. Pp. 204, with illustrations. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1953.

This excellent book has been written specifically to aid the average mother in satisfactorily nursing her infant. Information included is designed to encourage breast feeding and to give the normal woman all the knowledge she needs to nurse her infant. The advantages of breast feeding, including its psychological values, are also presented. Information concerning nursing brassières, nipple shields, and other equipment used by nursing mothers is given. There are also specific instructions for the preparation of the breasts during pregnancy. The value of the book is enhanced by the inclusion of a comprehensive list of questions and answers. An effort is made to dispel the many superstitions and false notions about breast feeding. Every expectant mother and every mother with a newborn infant could read this book with advantage.

Diseases of the Liver, Gallbladder and Bile Ducts. Volume I and II. By S. S. Lichtman, M.D., F.A.C.P., Assistant Professor of Clinical Medicine, Cornell University Medical College, New York. Third edition. Cloth. \$22 per set. Pp. 608; 609-1315, with 223 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

As in the previous editions, Dr. Lichtman reveals his extensive knowledge of the literature on hepatic and biliary diseases. The wide acceptance of the previous editions attests the reliability of the author's material, which begins with the structure of the liver and ends with the treatment of biliary tract diseases. This book is a veritable encyclopedia of all the literature that has been published to date on diseases of the liver. The author critically comments on the contributions and justifiably takes exception to some of the older concepts that have been presented by previous students in this field. Each chapter has been enlarged, and the therapy has been put at the end of each chapter, wherever possible. In the chapter on cirrhosis of the liver, the author discusses its complications and the controversial aspects of the therapy. He concludes that corticotropin (ACTH) and cortisone are not of great value in the therapy of this disease. The student in this field, who would like to know what has been published on the whole problem of liver and gallbladder and bile duct disease, will find an

extensive bibliography in this outstanding reference book. It is a necessary addition to any medical library but particularly to that of the physician who deals with liver and biliary diseases in practice.

The Hypertensive Disorders of Pregnancy. By Ernest W. Page, M.D., Associate Professor, Obstetrics and Gynecology, University of California School of Medicine, San Francisco. Publication number 188, American Lecture Series, monograph in American Lectures in Circulation, edited by Irvine H. Page, M.D., and A. C. Corcoran, M.D. Cloth. \$3.75. Pp. 120, with 2 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois; Blackwell Scientific Publications, Ltd., 49 Broad Street, Oxford, England; Ryerson Press, 299 Queen Street, W., Toronto 2B, 1953.

This monograph has three main chapters: (1) clinical aspects, (2) physiological and biochemical changes in normal pregnancy and toxemia, and (3) etiology of toxemia. Page has modified the classification of toxemias recommended by the American Committee on Maternal Welfare. He divides them into two main groups: (1) specific toxemia of pregnancy, including (a) preeclampsia (nonconvulsive) and (b) eclampsia (convulsive); (2) clinical entities symptomatically related to toxemia, including (a) generalized edema of pregnancy (not accompanied by hypertension or proteinuria), (b) essential hypertension and pregnancy, with and without superimposed toxemia, (c) primary renal disease (any type) and pregnancy, with and without superimposed toxemia, and (d) post-toxemic recurring hypertension in multiparas. He maintains that eclampsia without hypertension or proteinuria is as much a misnomer as eclampsia without convulsions and that uncomplicated disturbances of salt and water balance during pregnancy should be segregated as a clinical entity distinct from preeclampsia. He emphasizes that severe toxemia is characterized primarily by a widespread damage to small blood vessels and that the parenchymal lesions are largely secondary to the vascular disturbance. The composite pathological picture of fatal eclampsia is not duplicated in its entirety by hypertensive disease alone nor by any other known disorder, although the individual morphological lesions may resemble those of some other disease.

Page also points out that the greatest controversy regarding the treatment of eclampsia has revolved about the choice of drugs, while the question of when and how to deliver the child of a woman with toxemia really constitutes the most important decision. The selection of drugs is not so important as the amount of the agents, the methods of using them, and the avoidance of measures that a knowledge of pharmacology and physiology warns us may be harmful. He then outlines his own management of patients with eclampsia. This book contains a vast amount of useful information about the hypertensive disorders of pregnancy. At the end is a well-selected bibliography, including many papers written by the author. This book is authoritative because Page has done much investigative work in this field. It is highly recommended to everyone interested in obstetrics, pathology, and internal medicine.

Nutritional Studies in Adolescent Girls and Their Relation to Tuberculosis. By Joseph A. Johnston, M.D., Pediatrician-in-Chief, Henry Ford Hospital, Detroit. Cloth. \$7.50. Pp. 320, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad Street, Oxford, England; Ryerson Press, 299 Queen Street, W., Toronto 2B, 1953.

This book is a compilation of research findings over a long period of time concerning the storage of nitrogen and its effect on the course of tuberculosis in adolescent girls. The author points out that negative balances or inadequate retention are frequently associated with failure to heal but that this cannot always be established. An extensive comparison of roentgenographic findings and of the nitrogen balance is recorded. The author calls attention to the many variables that must be considered, such as massiveness and repetition of infection, which cannot be accurately measured. Although not a large book, it represents a tremendous amount of work, including a discussion of the amounts of calcium and vitamin D necessary for normal storage in adolescent girls. The author concludes that the best way to prevent endogenous reinfection in tuberculin reactors is the insurance of normal retentions of nitrogen and calcium. This involves an adequate intake and consideration of all fac-

tors that influence their utilization. The book is well written, and includes many case histories, graphs, and tables. It should prove valuable to any physician who is interested in tuberculosis.

Emergency Surgery. Bernard J. Ficarra, A.B., Sc.B., M.D., supervising editor. Cloth. \$18. Pp. 1000, with 578 illustrations. F. A. Davis Company, 1914-16 Cherry St., Philadelphia 3, 1953.

This monograph covers emergency surgery in a complete manner and is profusely illustrated. A number of the subjects discussed, however, do not appear to come within the province of emergency surgery. For instance, the management of acute low back pain is discussed in detail, even to the surgical treatment of a ruptured intervertebral disc. Persistent hiccup, although disturbing, could hardly be considered an emergency. These are minor defects; on the whole, the authors have prepared an excellent and very complete monograph, which should be in the library of everyone who treats emergencies and should be of value to all general practitioners. As an illustration of the completeness and progressive character of the monograph, excellent chapters on the management of the injured following atomic disaster and on emergency surgery of air casualties are included.

A Ray of Darkness. By Margiad Evans. Cloth. \$3. Pp. 191. Roy Publishers, 30 East 74th Street, New York 21, 1953.

The ray of darkness is the epilepsy that abruptly entered the life of the author in the middle of her career as an English writer and poet. The story is autobiographical, introspective, and beautifully written. She describes the subjective phases of her seizures with crystal-clear fidelity. Like Job, she searches for an understanding of this calamity, and, when prose fails, she has in reserve her delicately phrased poetry. As an exposition of what epilepsy can mean to a sensitive, honest, and courageous mind, the book is unique. Incidentally, it points out the difficulties that arise from divided medical opinions and ineffective therapy. Lacking a happy ending, the book nevertheless is food for the minds of those who enjoy fine writing or who can profit from reliving with a patient the experience of a devastating illness. Physicians, psychologists, medical social workers, and many of the reading (and thinking) public, including the millions who are related to epileptics or concerned with their care, will want to read this book.

Adventures in Physiology with Excursions into Autopharmacology. Selection from scientific publications of Sir Henry Hallett Dale, G.B.E., F.R.S., M.D. With introduction and recent comments by author. Cloth. \$19.50. Pp. 652, with illustrations. [The Macmillan Company, 60 Fifth Ave., New York 11; Pergamon Press, Ltd., 2, 3 & 5 Studio Place, Kinnerton Street, Knightsbridge, London, S.W.1, 1953.]

Of the 253 published works by this author, only 30 have been chosen for this volume. The papers chosen relate mainly to the two lines of research that have dominated the author's scientific activity: the action of epinephrine and acetylcholine and their relationship to the chemical phase in the transmission of the effects of nerve impulses and the action of histamine and the general effects of this compound as related to its contribution to local and general reactions, by which the organism as a whole and its separate tissues respond to various immunological, chemical, or physical assaults on the integrity of their living cells. In addition to the scientific papers, the volume contains a complete bibliography of the author's work from 1899 to the present and an admirable introduction which relates the body of the book to incidents in the author's scientific life. The papers here collected were written between 1906 and 1938, and they have been reproduced without alteration. The comments that Sir Henry has appended to each of the papers are especially helpful. These comments bring evidence and ideas from the past into relation with present knowledge and theories. It is hoped that in a second printing of this volume a short biographical sketch of the author will be included. This book is recommended to all who are interested in recent developments in physiology, pharmacology, and experimental pathology.

QUERIES AND MINOR NOTES

TOXICITY OF AMINOPHYLLINE

TO THE EDITOR:—Recently I treated a 3½-year-old boy for asthma and bronchitis by prescribing use of an Aminet (containing aminophylline, pentobarbital sodium, and benzocaine) suppository, child size. One-half hour after the first suppository was inserted into the rectum, the child became pale and limp. His heart rate rose to 140, and this condition persisted for three hours. It looked as though the child were going to die. He was placed in an oxygen tent and treated supportively. He responded promptly. I treated another child 2 years of age for a similar condition. This patient presented the same picture plus vomiting. His wheezing cleared up, but he died in spite of supportive therapy. An autopsy revealed no major abnormalities. Microscopic studies revealed a fulminating virus infection of the lungs. I feel that the aminophylline contributed to his demise. An initial dose of one-half a suppository would be safer. Have any cases been reported in which death could have been due to aminophylline used in this way?

Nerio W. Pioppi, M.D., Southbridge, Mass.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

ANSWER.—The suppositories in question contain 0.25 gm. of aminophylline, 0.05 gm. of pentobarbital, and 0.03 gm. of benzocaine. Severe reactions, with a few deaths, have been reported from the use of aminophylline intravenously, but no recorded instances are known of severe reactions to aminophylline other than vomiting, which is not uncommon when it is given by rectum in either suppository or liquid form.

When judged by the adult dose, which is usually given as from 0.25 to 0.50 gm., a dose of 0.25 gm. for a child of 3½ years is a large dose, and it is not impossible that, if the aminophylline were absorbed rapidly, untoward symptoms might result. It is possible that the severe reactions in both of these cases were caused by aminophylline. This is, however, not proved. Severe sensitivity to cocaine derivatives is not uncommon, and it could be that the trouble in these patients was due to benzocaine. An initial dose of one-half or two-thirds of a suppository is certainly safer, and probably sufficient, for a 3-year-old child. If the reactions in these patients were caused by aminophylline, they were probably due to drug toxicity; if caused by benzocaine, to allergy to the drug.

ANSWER.—It is highly doubtful that the reactions described by the inquirer were due to allergy. If it were an allergy it would be most likely due to the base in which the aminophylline is incorporated. In the first case described the symptoms are most suggestive of cardiac excitatory effects from the aminophylline. The second case apparently presented a picture of cerebral excitation. Death due to intravenously administered aminophylline has been described. Since rectal administration may also produce rapid absorption, the similar toxic effects are also possible. The inquirer's suggestion that "an initial dose of one-half a suppository would be safer" is a most practical one.

RELIABILITY OF THE HAEMOSCOPE

TO THE EDITOR:—How reliable is the Haemoscope?

E. D. Huntington, M.D., Chicago.

ANSWER.—The Haemoscope is an electric photometer for determining the number of cells suspended in solution by measuring the scattered light. The usefulness of this instru-

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

ment is limited by the fact that the count is affected by the cell size and also by the cell shape. At present it is not known how serious this defect may be in evaluating red blood cell counts in pathological conditions. The most modern instrument compensates for variations in cell size over a limited range, i. e., from 7.2 to 8.8 μ average diameter. A comprehensive appraisal of the Haemoscope may be found in the *American Journal of Clinical Pathology* (23:731-745, 1953). An editorial in the same issue on page 800 also deals with this subject.

CORONARY DISEASE AND RESUSCITATORS

TO THE EDITOR:—I encountered a case of recurrent coronary occlusion in a 65-year-old man, who was given oxygen by a Pulmotor apparatus for 10 minutes by a police emergency squad prior to the arrival of a physician. The patient died six minutes later. Autopsy showed there was good oxygenation but a tremendous over-insufflation of the lungs, which bulged well into the mediastinum. The heart showed coronary stenosis and an old myofibrosis. Has maladministration of oxygen by a Pulmotor with excessive oxygen tension been known to precipitate death? M.D., New York.

ANSWER.—The use of resuscitators in cases of acute coronary occlusion has become rather common practice. It has been reported that older devices such as the one sold as the Pulmotor did develop pressures that were felt to be excessively high. The modern resuscitator automatically provides for inhalation and exhalation. The Council on Physical Medicine and Rehabilitation of the American Medical Association has established minimal requirements for the acceptance of resuscitators and inhalators. Such devices as accepted by this Council conform to these requirements: The positive pressure in such devices at the face mask may not exceed 20 mm. Hg and the negative pressure may not exceed 9 mm. Hg. It is doubtful that apparatus that conforms to the Council on Physical Medicine and Rehabilitation's minimal requirements when used properly could be a factor in precipitating death in the situation mentioned in the inquiry. Some modern resuscitators are built to provide active inspiratory and expiratory phases through the application of positive and negative pressures alternately. Other units provide an active inspiratory phase due to the positive pressure they develop, and passive expiration occurs at the end of the positive pressure phase.

USE OF TOWELS ON EDGES OF INCISIONS

TO THE EDITOR:—Has any investigative work been done on use of skin towels on the edges of surgical incisions during surgical procedures? Some persons say that, when these towels become saturated with blood, they readily transmit organisms. Are there any references available to work that has been done to test this practice?

John C. Meyers, M.D., San Francisco.

ANSWER.—The use of towels on the edges of surgical incisions is an apparently undocumented convention. Originally the towels were moistened with germicide and presumably contributed to asepsis (Von Bergmann, E.: *Jahrb. klin. Chir.* 1:147, 1889). The clinical observation of blood oozing through a towel fixed to the skin edge or bile staining the skin beneath such a towel suggests the bacteriological folly of using the conventional dry towel.

Pads made by interleaving a sheet of cellophane are used (Lahey, F. H.: *J. A. M. A.* 104:1990 [June 1] 1935) to protect the skin or to wall off the viscera. A bactericidal vinylite resin has been described that is applied in the operating room to form a film that adheres to the skin (De Bakey, M.; Giles, E. J., and Honold, E.: *Surg., Gynec., and Obst.* 74:499, 1942) and through which the incision is made. Studies showed that bacteria

were recoverable from the cut edge of the skin in 16.6%, the surfaces of the film remaining sterile. Sterile vinylite drapes are commercially available (Gerspacher; T. S.; Fowler, H. D., and Rolf, D. E.: *A. M. A. Arch. Ophth.* 45:673 [June] 1951) with adhesive areas for attachment to the skin. Because the plastic films are impervious, use of these techniques is a logical means for excluding the skin or isolating septic portions of a surgical procedure as use of rubber gloves.

PNEUMOTHORAX

TO THE EDITOR:—*What is the composition of the oil and wax formula used intrapleurally in cases of pneumothorax?*

M.D., Michigan

ANSWER.—The most commonly used preparation for oleothorax therapy is mineral oil that contains 1 to 5% Gomenol (a partially volatile oil distilled from the leaves of a tree [*Melaleuca viridiflora* Brong. and Gris.] that grows in countries around the Indian Ocean). Other oils that have been used include paraffin oil, olive oil, and cottonseed oil, all of these with or without added Gomenol, 1 to 10%. A 2 to 10% solution of iodine in vegetable oil (Iodipin) was extensively used in Germany at one time. This form of therapy in the treatment of pulmonary tuberculosis has been practically abandoned in most institutions because of the high rate of complications and the advent of improved methods of treatment, including pulmonary resection.

ELECTIVE STERILIZATION OF WOMAN

TO THE EDITOR:—*The surgical staff at a hospital recognizes multiparity as an indication for elective sterilization if the woman is over 20 years of age and has at least four living children and if she and her husband request the procedure in writing. A sharp difference of opinion has arisen over the best procedure for sterilization. One group feels that a tubal ligation done a day or so after delivery is the only acceptable procedure. A second group practices salpingectomy rather than simple ligation because of the occasional failures encountered with any type of ligation. A third group has the patient return six or seven weeks after delivery for a total abdominal or vaginal hysterectomy. An opinion would be appreciated as to which of the three procedures outlined above should be used in good risk patients.*

M.D., New York.

This inquiry was referred to two consultants, whose respective replies follow.—ED.

ANSWER.—If the policy of the private hospital as reported here is not against the law of the state in which it exists, written consent of the husband and wife should be sufficient. The only question remaining to be explored is the type of procedure that it is best to employ. From the standpoint of permanence and simplicity, bilateral salpingectomy would appear the most reliable. There would seem to be no persuasive reason why hysterectomy should be resorted to. The possibility of predecease of the husband while the wife is still in the childbearing age must be considered. In that case, if the wife should remarry, her second husband might insist on her bearing his own children. Under such circumstances, a prior bilateral salpingectomy would be fatal to the hopes of this second marriage. With this contingency in mind, it might be wiser to have chosen a simple tubal ligation in the first place, since such a procedure usually establishes a situation that may be reversed if the circumstances require it.

ANSWER.—The simplest and safest procedure for sterilization after delivery is tubal ligation within 24 hours. This operation can easily be done under direct infiltration or intravenous anesthesia through a very small abdominal incision below the umbilicus. The Pomeroy procedure is the most certain method of tubal operation, because the incidence of failure is about one in 200 cases. This operation does not prolong the patient's hospital stay. In view of the excellent results of the Pomeroy method of sterilization and its simplicity and rapidity, there is no need to perform bilateral salpingectomy, which can be a bloody procedure immediately after delivery. Likewise, it is

not justifiable to have a patient who has several children at home return for another hospital sojourn even for a simple procedure even if the expense is left out of consideration. The removal of a uterus abdominally or vaginally is a major procedure and carries some risk, although it is slight. Even if there were no risk of mortality or morbidity, a hysterectomy should not be carried out for the sole purpose of sterilization in a young woman. The only time a normal uterus may be removed for purposes of sterilization is at the time of cesarean section in a woman who has a large family and is near the end of her reproductive career.

ONE, HIGHBALL AND DUODENAL ULCER

TO THE EDITOR:—*I am 50 years of age and for several years I have enjoyed a scotch and soda before dinner. For three weeks I had indefinite, vague, no-relation-to-meals gastrointestinal discomfort. A gastrointestinal series showed a definite small 2 mm. projection on the greater curvature of the duodenal cap, which the roentgenologist states is probably a small duodenal ulcer. Does the relaxation from one predinner drink overbalance the potential harm supposedly caused by alcohol?*

M.D., New York.

ANSWER.—A patient with an active duodenal ulcer should not have scotch and soda before dinner, or before a meal, regardless of well-being that is brought about. The stimulation of the parietal cells of the stomach by the alcohol would more than outweigh the sense of well-being that would result from the presumed "quieting down" of the emotional household.

AMAUROTIC IDIOCY

TO THE EDITOR:—*In the Queries and Minor Notes of THE JOURNAL, Oct. 31, 1953, page 894, is a question about the possibility of recurrence of amaurotic idiocy (Tay-Sachs disease) in future children of a couple who have already had one such child. The statement is made that "Little is known regarding the relative importance of the sperm and the egg in the transmission of human traits." Amaurotic idiocy is currently considered to be due to a recessive gene, and thus an affected person must receive this gene from both parents. The chances are one in four that any subsequent child of this couple will have amaurotic idiocy. If artificial insemination with a nonrelated Jewish donor is carried out, the chance for the infant having the disease is probably less than one in 500; if a non-Jewish donor is used, then the chance becomes exceedingly small.*

Ray C. Anderson, M.D.
University of Minnesota
The Dight Institute for
Human Genetics
Minneapolis 14.

TO THE EDITOR:—*Your consultant's answer to the query on infantile amaurotic idiocy (J. A. M. A. 153:894 [Oct. 31] 1953) deserves amplification. There is good evidence that this disease shows simple recessive inheritance (Slome, D.; J. Genetics 27:363, 1933). Since the family in question has had one affected child, both parents must carry the recessive gene and the chances of any subsequent child developing the disease are one in four. Furthermore, the diseased child must receive the pathological gene through both the egg and the sperm.*

With regard to the question of artificial insemination, if the disease frequency in Jews is of the order of 1 in 10,000 (probably an over-estimate), the risk that a child of this mother sired by a man unrelated to the parents would develop this disease is about 1 in 400. If the donor were non-Jewish, the risk would be appreciably lower than this.

SPINAL ANESTHESIA IN CESAREAN SECTION

CRITICAL ANALYSIS OF ABOUT 1,200 CASES WITH NO MATERNAL MORTALITY

Donald W. deCarle, M.D., San Francisco

Although employed in cesarean section throughout the country since 1941, spinal anesthesia was not given extensively for this procedure at Children's Hospital in San Francisco until 1947. Since then, however, it has practically replaced all other forms of anesthesia for cesarean section at this institution. As shown in table 1, there were 13,508 deliveries at Children's Hospital during the six year period from 1947 through 1952. These included 1,427 cesarean sections, of which 1,236 were performed under spinal anesthesia, for an incidence of 86.61%. The shift to spinal anesthesia can be attributed only to some very definite advantages, which the majority of the obstetric surgeons of this staff recognized. The more important of these are, first, the complete absence of all irritating drugs and the untoward complications associated with inhalation anesthesia.¹ In the 18 months prior to January, 1947, one patient died from inhalation of vomitus, following inhalation anesthesia, and three others required aspiration by bronchoscope to relieve complications from the same cause. Second, the rapidity with which it takes effect gives it added advantages, even over local anesthesia, in the presence of fetal distress. Third, the almost complete absence of any detrimental effect upon the infant makes it particularly desirable in the presence of prematurity. This conclusion is shared by others, including Eastman.² Downing³ has shown a 25% decrease in fatality among premature infants by the use of caudal anesthesia. Masters and Ross⁴ found an even higher rate with conduction anesthesia in general.

Prematurity is not unusual in cesarean section. The presence of bleeding from placenta previa or premature separation of the placenta; the onset of premature labor, either with or without the rupture of membranes in patients for repeated or elective section; and the presence of a progressive toxemia results frequently in the delivery of a premature infant. Errors in estimation of the fetal age also accounts for a substantial number of premature infants. However, a more accurate method of estimating

the age of the fetus in utero, using roentgenogram, was recently demonstrated by Adams; this should be helpful in obviating this latter group. A study of data based on a division of these premature infants into two groups, those who survived premature delivery complicated by such factors as early labor and those who were delivered prematurely because of faulty estimation of fetal age, reveals that the mortality in the first group was high (21 deaths among 111 infants). The pediatric staff believes, however, that this rate would have been higher had any form of general anesthesia been used. In the second group only two neonatal deaths occurred. A fourth, and one of the most important advantages of spinal anesthesia, is the uniform excellent muscular relaxation it creates. This is definitely advantageous in any type of abdominal approach but is particularly suitable for the low transverse or Pfannenstiel incision. Used for 351 of our patients, the Pfannenstiel incision, as opposed to the midline incision, lends itself especially well not only to the low cervical uterine incision but also to any of the extraperitoneal procedures (of which there were 39 in this group). It has been previously shown that one of the chief advantages of this low transverse incision is the still further reduction in the amount of spinal anesthesia required.⁵ This, in turn, results in widening the margin of safety of the low spinal type of anesthesia for cesarean section.

METHOD OF ADMINISTRATION

The selection of the drugs used for spinal anesthesia and the technique of their administration is subject to considerable variation in different parts of the country. Credit for a large part of the favorable results obtained in this particular group can be attributed to a very definite and, in so far as possible, uniform routine. A combination of procaine and tetracaine (Pontocaine) hydrochloride as a single injection was given in each of the 1,236 cases. By 1947, when the first of this group was delivered, it was widely known that the pregnant woman, due to the

increased intra-abdominal pressure, was particularly vulnerable to spinal anesthesia in amounts ordinarily employed in surgery in general. Therefore, no one of these patients received more than 50 mg. of procaine or 10 mg. of tetracaine. Many received less, especially when the transverse abdominal incision was employed. As little as 35 mg. of procaine and 5 mg. of tetracaine was found to be adequate in many of these patients.

TABLE 1.—*Cesarean Sections at Children's Hospital 1947 to 1952 (Inclusive)*

	Total Deliveries	Cesarean Sections	Percentage	Spinal	General	Caudal	Local
1947	2,460	251	10.2%	183	51	11	6
1948	2,287	283	12.3%	248	18	10	7
1949	2,286	216	9.5%	195	9	11	1
1950	2,236	209	9%	193	8	7	1
1951	2,144	224	10.4%	199	17	7	3
1952	2,095	244	11.6%	219	15	7	2
Totals	13,509	1,427	10.54%	1,238	118	53	20

The second important step in the successful administration of spinal anesthesia was the preparation of an intravenous route by the anesthesiologist. This was essential for, first, the routine intravenous administration of fluids, namely, 5% glucose in this group, in amounts up to 1,000 cc.; second, the injection of oxytocics; third, the administration of further anesthesia when necessary; and fourth, as an immediately available avenue for blood transfusion. The fact that hemorrhage is the number one killer today lends further importance to this procedure. Although spinal anesthesia provides increased uterine tone with usually diminished blood loss, every obstetric patient in whom surgery was contemplated at Children's Hospital was treated as a potential emergency. A routine check for anemia was required for every patient on entrance. Crossmatching was done whenever it was deemed necessary by the surgeon-anesthesiologist team. Table 2 gives the estimated blood loss among the patients in this group. It also includes the blood transfusions given. Out of 178 of these transfusions, one patient alone, with lower nephron nephrosis, received nine units of whole blood. At least one and usually two emergency units of type O-Rh negative blood were constantly available. Only one severe transfusion reaction occurred in the entire group in which 135 patients were reported as Rh negative.

Still another important responsibility of the anesthesiologist was the constant observation of the blood pressure for any marked change. Sudden hypotension ("spinal shock") occurred frequently in this particular group where spinal anesthesia was given as a single dose. In order to avoid the side-effects of such complications, one or more of the vasopressor agents was given in minimal dosage almost routinely to maintain or restore the blood pressure to a safer level. Of equal value was the immediate and rapid delivery of the infant in a large majority of those patients whose blood pressure was unstable. The time element varied from 4 to 12 minutes, depending on

the operator. This not only protected the infant from anoxia in the presence of such a marked fall in blood pressure but reduced immediately the strain on the maternal heart. Some 46 of the patients in this group, with marked hypotension preceding the administration of the anesthesia, were also carried through surgery by this method without any serious complication.

In the occasional patient, a marked hypertension occurred. Therefore, extreme caution in the administration of the various oxytocics was observed when a vasopressor agent had been previously given.⁶ The procedure of giving oxytocin (Pitocin) directly into the uterine musculature was abandoned except in 11 of these patients. However, two patients to whom an intravenous injection of ergonovine (Ergotrate) maleate was administered after ephedrine therapy showed abrupt rises in systolic pressure to over 200 mm. Hg. Headache with some retching was noted. Because of the increased danger with such a reaction, special care was used in the supervision of the 48 patients in whom systolic pressure was over 140 mm. Hg before the anesthetic was given.

MATERNAL MORTALITY

The incidence of cesarean section, as that of maternal mortality, varies considerably in different sections of the country. In 1938, Bell⁷ reported the findings of the Maternal Mortality Committee of the San Francisco Gynecology Society, for the years 1932 through 1938. Included in these were the statistics on the number of cesarean sections done in the San Francisco hospitals collectively and individually. As shown in table 3, there were 2,592 sections done in the San Francisco hospitals during that time for an incidence of 5.63%. Of these, 20% were classical. There was a total of 49 maternal deaths. Sepsis was the leading cause, followed in turn by toxemia, hemorrhage, and embolism. The last group of figures comprise those from which the present study was taken. As shown here, 1,427 cesarean sections were performed at Children's Hospital from 1947 to 1952, inclusive, for an incidence of 10.56%. There were three fatalities during this time, following cesarean section, for an incidence of 0.21%. However, two of these were operated upon in the presence of a spontaneous subarachnoid hemorrhage.⁸ The third patient died as the re-

TABLE 2.—*Estimated Blood Loss and Transfusions*

	Estimated Blood Loss			Blood Transfusions

Totals	222	25	4	161	12	5

sult of an afibrinemia, following an extensive premature separation of the placenta. All three were delivered under general or local anesthesia and therefore are not included in this group under consideration.

RESULTS OF LOWERED MORTALITY

A comparative study of these statistics brings us to some definite conclusions. First, although the incidence of cesarean section was far less 15 years ago, the maternal

6. Greene, B. A., and Barcham, J.: Cerebral Complications Resulting from Hypertension by Vasopressor Drugs in Obstetrics, *New York J. Med.* 49: 1424-1426 (June) 1949.

7. Bell, T. F., and others: Maternal Mortality in San Francisco, Oakland, and Berkeley, Calif., 1932-1938, Inclusive, read before the American Congress on Obstetrics and Gynecology, Cleveland, Sept. 11-15, 1939.

8. deCarle, D. W.: Pregnancy and Cerebrovascular Complications, *West. J. Surg.* 57: 181-191 (May) 1949.

mortality was infinitely higher. Second, the greatly lowered incidence during 1947 to 1952 could have been brought about only by certain very definite factors. The most important of these can be summarized as follows: The training of personnel in surgical and anesthetic procedures has improved; there has been an increase in the use of newer surgical techniques such as low transverse uterine, extraperitoneal, and transverse abdominal approaches; improved anesthetic agents are being administered more competently by better trained personnel applying increased knowledge of the physiology of water balance, vasopressor substances, and oxytocics; the handling of whole blood has improved due to the growth of blood banks, revision of blood groupings, and discovery of the Rh factor; sulfonamides and antibiotics add significantly to the control of infection; and methods of roentgenogram pelvimetry and soft tissue diagnosis has been improved.

Third, these factors in turn, by lowering the fetal and maternal mortality in cesarean section, have contributed lessened mortality for mother and child in general. Lastly,

number for the same patient is possible. Data accumulated over the six-year period from 1947 to 1952 reveal that 331 women had a second cesarean section; 97, a third; and 16, a fourth. It is evident that repeated sections can no longer be considered unusual. In the entire group reported by Bell⁷ in 1938, there were only five repeated sections. On the other hand, in the present group, as shown by table 4, the repeated sections actually outnumbered all other indications, especially in the last three years, with a total of 444. With these figures in mind, the marked increase in the incidence of cesarean section in a private hospital such as Children's is more easily understandable.

Further study of table 4 shows other factors that may have affected the incidence of cesarean section in this group. Among these, rheumatic heart disease should have no place. Only when there is a definite obstetric indication should cesarean section be done in such a patient and then never under spinal anesthesia. Trial labor, as shown by Hunt,¹³ is extremely valuable in the evaluation of certain so-called obstetric imponderables. There were

in so doing, they have widened the indications for this procedure, thereby increasing the incidence of cesarean section. Harris and his group⁹ have arrived at a similar conclusion in a comparative study of two groups of cases taken from one of the Los Angeles hospitals. Although their incidence of cesarean section was 9.79%, they had 0.05% maternal mortality from cesarean section as opposed to 0.08% among the patients delivered from below. Lull,¹⁰ in 1943, made a similar comparison, as did Tollefson¹¹ with an 11% cesarean incidence. In a more recent study Lull and Ullery,¹² in whose study the incidence was 7.2%, explained the increase in cesarean section upon a definite trend toward this procedure in the presence of a toxemia, placenta previa, and premature separation of the placenta. Another reason given by them is the changing attitude toward repeated sections. In the old classical technique, a second section was thought to be more than sufficient in any one patient. In many instances, the patient was delivered from below, following a previous section, sometimes with serious results. The low cervical approach, whether extraperitoneal or transperitoneal, combined with the administration of antibiotics and whole blood has so improved the technique and diminished the risk of repeated sections that an increasing

279 such trial labors in this group that were considered entirely satisfactory. There were another 31 that were preceded by attempted induction of labor with very unsatisfactory results. Probably, a spontaneous labor could have resulted in delivery from below of a substantial percentage of these patients.

POSTOPERATIVE COMPLICATIONS

The postoperative complications that occurred in these patients were of two types: those that were the direct result of surgery and those complications that arose from the anesthesia itself. In three patients of the first group postoperative phlebitis developed; acute distention with early signs of obstruction developed in five; two had pneumonitis, and one patient had lower nephron nephrosis. The diagnosis for another patient whose systolic

blood pressure was 50 mm. Hg or less for 24 hours following surgery was adrenal apoplexy. In two patients, dehiscence occurred in the wounds, following midline incisions. One patient who had had a Pfannenstiel type of incision had to be returned to surgery to be evacuated of a large subfascial hematoma. Rupture of the uterus occurred in none of these patients. Only two patients in this group who were operated upon were allowed to deliver from below in subsequent pregnancies.

In the second or postspinal group of patients, none of the more serious neurological complications so frequently described in the literature¹⁴ developed. Four patients, however, complained bitterly of persistent backaches at the site of the injection. All but one of these had recovered satisfactorily by the end of six weeks. While incontinence was only transitory in 1 patient, 3 required retention catheters, and 23 others required repeated catheterization. Aside from these, the most serious kidney complication in the entire group followed a general rather than a spinal anesthesia.

Eighteen patients complained of moderately severe headache, and in 45 others the headache was definitely severe, for an incidence of 5.09%. According to Thorsen,¹⁵ patients with spinal headaches should be divided into three separate groups for purposes of treatment. Least important of these is the so-called miscellaneous group in whom headache may arise from multiple causes and should respond fairly satisfactorily to the ordinary means of treatment. The first 18 patients probably belonged to this group. The other 45, however, should have been separated into those with headaches due to decreased cerebrospinal pressure resulting from loss of cerebrospinal fluid, and those with headaches associated with an increased cerebrospinal pressure resulting from

a combined closure of the dural puncture wound and stimulation of the choroid plexus. Because of the associated dehydration, the first condition reportedly responds well to the administration of a hypotonic saline solution, 0.5% normal. The second responds well to administration of a hypertonic saline solution, according to Thorsen.¹⁵ Unfortunately, these 45 patients, with few exceptions, were treated with a variety of drugs with very indifferent and unsatisfactory results.

It is worthy of note that the results of Wassermann tests were positive for only one patient, and here the cerebrospinal fluid was negative. In this regard, the department of anesthesiology urges that the obstetrician be familiar with not only the serology but also the history of any central nervous system disease present in his patient. This knowledge, they feel, may help avoid serious trouble for a busy anesthesiologist in an emergency involving such a patient.

COMMENT

Beginning in 1941, there was a definite shift to spinal anesthesia, according to Potter and Pender.¹⁶ This trend increased rapidly until 1943, when, according to these authors, 84% of all sections were done under this anesthetic. Since 1945, however, the number in all areas of surgery where spinal anesthesia has been used has dropped gradually. This may be attributed to the controversial position held by spinal anesthesia and the adverse publicity given it. The technique of spinal puncture unfortunately is comparatively simple, even for the untrained. Probably the greatest single cause of disastrous results from the use of spinal anesthesia is due to this very simplicity. There is danger when this form of anesthesia is administered by someone who is unfamiliar with the physiology of the drugs employed and the contraindications to their use and who is not able to recognize the early signs of serious trouble. Only administration by properly trained personnel can ensure successful results; this has been pointed out by Greenhill.¹⁷ Needless to say, all anesthesia used in our study was given by trained physician-anesthesiologists.

It is indeed unfortunate that a procedure as valuable as spinal anesthesia has become a paradox in medicine. To the obstetrician, it has distinct advantages in cesarean section as well as in vaginal delivery. The pediatrician states unequivocally that it surpasses any other type of anesthesia for the safety of the infant in cesarean section. This is especially true in the premature delivery where fetal anoxia is reduced to a minimum. On the other hand, even to the trained anesthesiologist, spinal anesthesia presents certain difficulties. The smaller and safer dosage, the constant improvement of the drugs used, and the improved techniques for their administration are lessening these difficulties.

The law, the public, and, at times, even the neurologist have placed the anesthesiologist and the obstetrician in the position of having to prove that spinal anesthesia is not the causative factor of certain untoward complications, rather than the reverse. Unless something is done, conduction anesthesia in general, at least in the state of California, may have to be discarded. This, in turn can mean an immediate increase in fetal mortality, especially in the premature group. The same would be true of ma-

ternal mortality. I believe that this can be done only by, first, preventing the use of conduction anesthesia by the untrained; second, by increasing the number of well-trained physician-anesthesiologists; and, thirdly, by alerting the public by publishing statistics of the kind presented here.

SUMMARY

An analysis is presented of 1,236 cases in which spinal anesthesia was given successfully for cesarean section with no maternal mortality. The advantages and disad-

vantages of the technique employed are discussed. Justification for the high incidence of cesarean section in this group is offered. Spinal anesthesia in the hands of the trained anesthesiologist is stated to be, in the opinion of the authors, the best form of anesthesia to date for both mother and infant in cesarean section. The importance is stressed of making every effort to educate the public to its advantages as long as the margins of safety can be constantly increased.

ELECTIVE APPENDECTOMY AT THE TIME OF CESAREAN SECTION

Elisabeth Larsson, M.D., Los Angeles

The story of appendicitis is a proud chapter in the history of medicine. In 1935, the disease took 16,142 lives in the United States. In 1940, the death rate from this cause was 12,999, and in 1945 the mortality dropped to 6,697. In 1950, 2,897 lives were lost from the disease. Comparison of these statistics is even more striking when it is observed that in the United States in 1935 one person died from appendicitis every 33 minutes, or a total of 44 a day, while in 1950 one died every three hours or eight persons a day. The mortality rate over a 15 year period, 1935 to 1950, dropped 85%. The rapid decrease in the death rate from appendicitis is due to: (1) improved medical care and surgical technique; (2) discovery and use of antibiotics; (3) nationwide health education that has caused an increasing proportion of patients to seek treatment early, before complications arise; and (4) prophylactic appendectomies during pelvic and abdominal surgery.

It is beyond the scope of this paper to consider in detail all of the factors influencing the remarkable downward trend in death rate from appendicitis. The fact, however, that in 1950 appendicitis took 2,897 lives in the United States indicates that there is still a need to improve the methods of coping with this disease and to widen their effective use. Elective appendectomy in conjunction with pelvic and abdominal surgery has gradually become an accepted and recommended procedure, but reluctance to perform a prophylactic appendectomy at the time of cesarean section still exists among surgeons. This presents a challenge that should be investigated to ascertain whether the premises on which this reluctance rests are valid.

It is the purpose of this paper to show the development and acceptance of elective appendectomy in conjunction with pelvic and abdominal surgery through a review of some of the literature and to answer the challenge of performing elective appendectomy with cesarean section by presenting a series of 20 cases of my own and a survey of 764 cases of other surgeons. All of these cases were without any significant complications attributable to the incidental removal of the appendix.

SURVEY OF LITERATURE

In 1908, Fischer¹ wrote, "For the last two years it has been my rule to remove the appendix when I opened the abdomen for other causes, where the condition of the

patient would allow this extra procedure." In 1910, McWilliams² reported a series of 1,411 appendectomies performed at the Presbyterian Hospital in New York from 1906 through 1909. Of these, 212 were done incidentally during laparotomies for other reasons. He said, "I have seen no list of such operations to prove that the removal of the appendix will prejudice recovery." In his own work he removed the appendix in 299 of the last 600 abdominal sections he had done for causes other than appendicitis or the removal of the appendix.

In 1911, Goldspohn³ published an article in which he quoted the experience of a number of surgeons who found it necessary to do appendectomies after other abdominal operations and who were beginning to advocate the elective removal of this "mischievous and useless organ" when the abdomen was opened for other reasons. In 1913, Goldspohn⁴ said, "Prophylaxis is becoming more and more the better part of the function of every medical man. . . . During the past ten years the appendix has been removed incidentally with constantly increasing frequency." Since then, the advisability of removing the apparently healthy appendix at the time of other abdominal surgery has been the subject of much discussion. Most surgeons now agree that it is a sound and advisable procedure when done judiciously. Adair⁵ states that "The removal of the appendix during laparotomy for other conditions, if the appendectomy does not entail any appreciable additional risk, is sound prophylaxis." Berkeley and Bonney⁶ remove the appendix in well-chosen cases.

From the Department of Obstetrics and Gynecology, College of Medical Evangelists.

Curtis,⁷ during the earlier years of his surgical experience, did elective appendectomies at gynecologic operations. His views were temporarily modified by a few disappointing cases, but he reverted to routine removal of the appendix, unless the procedure was contraindicated.

Marshall and Macer,⁸ in their review of the mortality in 10,622 operations done on the gynecologic service at the Los Angeles County General Hospital, found that the elective appendectomies undoubtedly influenced the fatal outcome of some of the cases. Fatalities occurred, however, in patients on whom the appendectomies were done after prolonged and difficult operations or in instances in which there were accidental errors in the technique of the appendectomy. Pratt,⁹ in reporting on morbidity after total hysterectomies at the Mayo Clinic, found that appendectomies performed simultaneously with total hysterectomies had no effect on morbidity and should be performed on all patients in whom there are no contraindications. Rosset and Conston¹⁰ found that

Decrease in mortality rate of appendicitis between 1935 and 1950.

in 12% of their cases there was asymptomatic appendicitis. They advise routine incidental appendectomy provided risk to the patient is not increased.

Taniguchi and Kilkenny¹¹ in a review of 532 cases found no complications attributable to the prophylactic appendectomy and advise the routine removal of the ap-

pendix in pelvic surgery whenever it is accessible. Te Linde,¹² in his book "Operative Gynecology," states that it is his custom to remove the appendix in all pelvic laparotomies except in those cases in which it appears inadvisable to prolong the operation. He also states that at occasional intervals acutely inflamed and even ruptured appendixes are found in women who have had previous pelvic laparotomies. Wharton¹³ states that "We routinely remove the appendix during all pelvic laparotomies, unless the condition of the patient does not allow the additional surgery."

When one considers the evidence in favor of appendectomy in gynecologic surgery, questions naturally arise regarding the indications for this procedure in cesarean section. The feeling among obstetricians, that the appendix should not be removed at cesarean section, probably stems from the fact that the mortality rate has been higher in appendicitis during pregnancy than when not associated with pregnancy. The significance of this high mortality rate has been shown by investigators who have found that with proper treatment the mortality among pregnant women with appendicitis is no higher than among those who were not pregnant.

Lloyd-Green,¹⁴ in her report from Australia, states that the mortality of appendicitis complicating pregnancy is the mortality of delay. De Voe, Day, and Ferris¹⁵ of the Mayo Clinic report a pregnancy at term complicated by ruptured appendix. Dr. Ferris states that the reason for the high mortality rate of appendicitis in pregnancy is that the diagnosis is arrived at too slowly. Maes, Boyce, and McSettridge¹⁶ remark that the pathological condition is usually aggravated by delay.

Te Linde¹⁷ also upholds this viewpoint when he states that "The mortality of acute appendicitis in pregnancy is greater than in the nonpregnant. This is due to delay in diagnosis. It is doubtful that the mortality would be greater if these women were operated upon as early as the nonpregnant. . . . It becomes clear, then, that the mortality of appendicitis that complicates pregnancy is the mortality of delayed treatment, and delayed treatment is due to difficulties in diagnosis in the pregnant woman." Warfield¹⁸ of the Georgetown University Medical School, Washington, D. C., remarks that the important concept to remember is that the mortality of appendicitis is the mortality of delay.

PERSONAL EXPERIENCE

My interest in the subject was aroused in 1939 when a patient who was to have her third cesarean section requested that an appendectomy be done at the time of the section. Having been taught, and firmly believing, that performing an appendectomy at the time of cesarean section is a hazardous procedure because of the danger of infection, I felt obliged to deny her request. The cesarean section and appendectomy were done by another physician, and the patient's postoperative course was uneventful.

In 1946 in a patient on whom I had done a cesarean section, appendicitis developed a few months later and necessitated an appendectomy. I could not help but feel that the patient who had the appendectomy at the time of the cesarean section was the more fortunate of the two. I performed the first appendectomy with a cesarean sec-

tion in 1947 and have done 19 similar operations since that time. Data on all of these cases are listed in the table.

In no instance was the appendectomy the indication for cesarean section. Each appendectomy was done electally and was secondary to cesarean section. Spinal anesthesia was used in 19 cases and cyclopropane in 1 case. The vertical skin incision was used in 17 cases and the transverse in 3 cases. The appendix is more accessible when the vertical incision is used. The low cervical cesarean section was the technique used in all cases. The transverse incision was used in the lower uterine segment in 19 patients, whereas the vertical was used in 1 in whom large veins were present laterally.

The technique used in removing the appendix consisted of ligating the appendix at the base with 000 ab-

Ten patients received 500 cc. of whole blood during surgery. Three of the more anemic patients received 1,000 cc., and seven were not given transfusions. All patients, with the exception of those in cases 1 and 2, received antibiotics for three or four days after surgery, and a few received them before surgery. Penicillin, procaine penicillin G (Crysticillin and Duracillin), and streptomycin were the antibiotic agents used. There were no infections, and the incisions all healed by primary union.

The morbidity was 15%. This is satisfactory considering the morbidity standard used; namely, that of the Joint Committee on Maternal Welfare. It is defined as temperature of 100.4 F (38 C) occurring on any 2 of the first 10 days post partum, exclusive of the first 24

sorbable (chromic) surgical suture, excising it, coating the stump with phenol, and inverting it with 00 absorbable (chromic) surgical suture in a pursestring fashion. The appendectomy was performed at the time of the first cesarean section in 8 of the cases, with the second section in 11 cases, and with the third section in one case. A myomectomy was performed in one patient (case 10). Three patients were sterilized by the excision of approximately 2 cm. of the middle portion of the tubes and by ligating and burying both of the cut ends of the tubes. The patient in case 20 had a 2 cm. window of the uterine scar. The incision was made over the previous scar. No difficulty was encountered in closing this incision.

All appendixes were studied by the laboratory; all were reported as normal, except the one from the patient in case 17. In that patient, a lipid granuloma of the appendix was found.

hours, and taken by mouth by a standard technique at least four times a day. There were three patients in the group whose postoperative temperatures were 100.4 F or above on two and three days after surgery. The patient in case 3 was operated for placenta praevia, and an appendectomy was done. She had a temperature of 100.4 F and 101.6 F (38.7 C) on two postoperative days. The patient in case 10 had a myomectomy and appendectomy with the cesarean section. Her temperature was 101 F (38.4 C), 100.8 F (38.2 C), and 100.4 F on the first, second, and fourth postoperative days, respectively. The patient in case 18 was a 40-year-old Negro woman who had a repeat cesarean section with sterilization. Her temperature was 100.4 F and 101.6 F on the second and third days, respectively. She left the hospital on the seventh day in good condition. The average hospital stay was six and seven-tenths days per patient. The shortest hospital stay was four days, and the longest was nine days.

EXPERIENCE OF OTHERS

In addition to the 20 cases from my own experience, I would like to present a survey of 764 cases from the practices of a number of surgeons with whom I have communicated and who have graciously given me permission to use their material and from the gynecologic and obstetric services of the White Memorial Hospital and the Los Angeles County General Hospital.

R. J. Thompson of Los Angeles states, "I am very interested in the work that you are doing on the problem of performing appendectomy at the time of cesarean section. In years past I have frequently followed such a procedure, and I have never regretted having removed an appendix at the time of cesarean section. I am convinced that, since we now have antibiotics available, this procedure can be made even a more safe one than in times past. For this reason I do not hesitate, when the abdomen is opened and cesarean section is performed, to remove the appendix."

J. C. Irwin of Los Angeles reports that he has been performing elective appendectomies at the time of cesarean sections since approximately 1930. He has been doing this supplemental surgery only if there were no complications of the cesarean section or pregnancy that would otherwise contraindicate such a procedure. He has performed more than 200 appendectomies at the time of cesarean sections and to his knowledge has had no complications attributable to this supplemental surgery. He feels that it is definitely the procedure to follow in such circumstances.

H. E. Tebbetts and associates of Whittier, Calif., have performed 110 appendectomies with cesarean sections during 1943 to 1952, inclusive. Antibiotics were given when indicated, and there were no infections. J. Naeslund of the Uppsala University, Uppsala, Sweden, has done elective appendectomies with cesarean sections since 1925; 263 cesarean sections were performed on his service from 1935 through 1952. Incidental appendectomies were done on 106 of these patients. The appendix had been removed previously in 68, and the condition of the remaining 89 was not considered suitable to allow the additional surgery. There were two deaths among the 106 patients who had an appendectomy with the cesarean section; 1 died of bronchopneumonia and the other of toxicosis gravis and uremia. There were no infections or complications attributable to the appendectomies.

W. F. Kroener and L. T. Hibbard of Whittier, Calif., performed 85 appendectomies with 101 cesarean sections between 1945 and 1952, inclusive. Of this group, the microscopic examination of the appendix revealed mild acute catarrhal appendicitis in one case, mild acute appendicitis in one case, and carcinoid of the appendix in one case. Antibiotics were given in 25 cases, while none were used with the remaining 60. There were no complications ascribable to the appendectomies, and the morbidity was only 14%. H. W. Henken of San Bernardino, Calif., writes: "Your question concerning the performance of an appendectomy at the time of a cesarean section is interesting. This problem first came to my attention when a patient on whom I performed a cesarean section came in the same year for an emergency

appendectomy. At the time of the cesarean section, the question of an appendectomy was discussed. Since that time I have done more than 50 appendectomies on selected cases at the time of the cesarean section. In no instance was there any significant change in the recovery of the patient."

F. O. Wood and G. L. Austin Jr. of Hartford, Conn., treated a series of 200 cases of appendectomy at the time of cesarean section without infection. Some of the pathological findings reported included acute appendicitis, fibrosis of the appendix, decidual reaction, carcinoid of the appendix, and oxyuria vermicularis.

In addition to the 20 cases described in the table, 7 other cases of appendectomy with cesarean section have been recorded at the White Memorial Hospital. There were no infections among these patients. Elective appendectomy at the time of cesarean section has not been done at the Los Angeles County General Hospital until this year. Since Jan. 1, 1953, six such operations have been performed without complication. By personal communication, a number of isolated cases performed with satisfactory results have been reported.

SUMMARY AND CONCLUSIONS

The data on 20 private patients on whom elective appendectomy was done with cesarean section are presented. A survey of 764 similar procedures performed by other surgeons is included. All of the operations were without any significant complications that could be attributed to the incidental removal of the appendix. The appendectomy was done only when the patient was in good general condition, when the anesthetic was well tolerated, when the cesarean section itself did not present any difficult or unusual time consuming features, and when the appendix was accessible. It is my opinion that in the well-chosen case an elective appendectomy at the time of cesarean section is a safe and desirable adjunct in the armamentarium for safeguarding the life and health of patients.

Carcinoma of the Vulva.—Although a relatively rare condition, this is the gynecological cancer most characteristic of old age. The fact that so many cases follow on an external vulvar dermatitis of long standing often has the paradoxical effect of delaying the diagnosis. The symptoms are regarded by the patient as further manifestations of the chronic martyrdom to which she has been subject, and advice is not sought until a late stage. The lymphatic drainage of the vulva is exceptionally free. Many anastomotic channels cross the midline, allowing the cancer to spread rapidly and bilaterally. The inguinal or iliac metastases are extremely painful, press upon, and not infrequently erode, the great vessels, and fungate readily. It is therefore most necessary to secure the prompt diagnosis and the adequate treatment of vulvar cancer. Radiotherapy is not generally useful: the response of the primary tumor is unpredictable, the production of much local necrosis is an unpleasant and not infrequent complication, and the secondary deposits in the nodes are resistant to treatment. The operative extirpation of the whole vulva with the lymph nodes on both sides is the treatment of choice and is usually well tolerated even by feeble old ladies. The immediate relief of pain and the improvement in general health are often quite remarkable.—W. I. Morris, M.D., *Gynaecological Disorders in Old Age, Practitioner*, November, 1953.

CHEMOTHERAPY OF PRIMARY ATYPICAL PNEUMONIA

Gordon Meiklejohn, M.D., Denver, Lieut. Col. William G. Thalman (MC), U. S. Army

and
Edwin H. Lennette, M.D., Ph.D., Berkeley, Calif.

Soon after chlortetracycline (Aureomycin) became available for clinical evaluation, several reports presented data showing that this drug is effective in primary atypical pneumonia.¹ The paper by one of us (G. M.) and Shragg^{1d} reported that a sharp difference was noted between the duration of elevation of temperature in a group of patients treated with chlortetracycline and in a comparable group treated with penicillin. Since that time we have had additional opportunity to use chlortetracycline in this disease and have consistently observed a prompt drop in temperature and rapid clinical recovery. Experience with chloramphenicol (Chloromycetin) and oxytetracycline (Terramycin) has been more limited, but results have been generally similar.

Partly because adequately controlled studies have been so few in number and partly because primary atypical pneumonia is a disease that is often of short duration even when no chemotherapy is used, there has been considerable reluctance in some quarters to accept the thesis that the therapeutic effectiveness of chlortetracycline in this disease has been established. It seemed advisable, therefore, when large numbers of cases of primary atypical pneumonia began to occur at Fort Ord, California, during the fall of 1950, to study further the effectiveness of chlortetracycline and to compare its effectiveness with that of chloramphenicol and of oxytetracycline. With these objectives, an investigation was initiated during October, 1950, and continued until March, 1951. During that time data were collected on 149 patients with a diagnosis of primary atypical pneumonia who were treated with one of the three antibiotics mentioned or with penicillin. The penicillin-treated group was regarded as the control group. Penicillin was used

in this role because it is generally held to have no therapeutic effect in primary atypical pneumonia and because its use tended to cancel out any advantage accruing to the other drugs in the event that patients with bacterial pneumonia were inadvertently included in the series.

MATERIALS AND METHODS

Type of Patients Treated.—The patients were military personnel, the majority of whom were engaged in basic training soon after induction into the Army. All were males and, with few exceptions, were in the young adult age group. All were patients at the Station Hospital, Fort Ord.

Diagnostic Criteria.—The criteria followed in making a diagnosis of primary atypical pneumonia have been presented elsewhere.² Patients were included in the study group only when one, or more than one, area of infiltration was observed in the chest roentgenogram. Patients with pneumonia were excluded from the study if (1) the temperature readings during the 24 hours before treatment was started failed to reach 100 F; (2) the patient's course suggested that spontaneous recovery was imminent; (3) the clinical and laboratory findings suggested a bacterial etiology; or (4) the results of serologic tests established a diagnosis of influenza. The purposes of this screening were to narrow the study group, insofar as possible, to patients with a single clinical entity and to exclude patients whose illness was so mild or so near to spontaneous termination as to make evaluation of drug effect impossible.

Cold Hemagglutinins.—Cold agglutination tests were done for most patients, but in the majority of instances serum specimens were collected during their hospital stay and consequently in many instances were taken prior to the period when cold agglutinins are most likely to reach maximal titer. For this reason no accurate figures can be given on the percentage of persons in whom significant titers were demonstrated. A substantial proportion of those persons whose total illness exceeded 10 days in duration were shown to have cold hemagglutinins in significant titer.

Dosage of Drugs.—Chlortetracycline, chloramphenicol, and oxytetracycline were given by the oral route in doses of 0.5 gm. every six hours, a total of 2 gm. daily. In line with earlier recommendations,³ those patients receiving chloramphenicol were given a priming dose of 2 gm. of drug when therapy was started. This procedure was not followed with the other two drugs. Penicillin was given in single daily intramuscular injections of 600,000 units of procaine penicillin. The duration of therapy was, in most instances, three to five days.

It was arranged that, when patients receiving penicillin had shown no substantial improvement or appeared more ill within 48 hours, or at any time thereafter, they

should be dropped from the control group. Administration of penicillin was then stopped and one of the other antibiotics was given. This arrangement removed from the study group those control patients whose illness was severest and made it impossible to calculate figures for the mean and median duration of illness. It is for this reason that the following analysis is based on the responses of patients during the 48 hours after treatment was begun.

TABLE 1.—Distribution of Patients with Primary Atypical Pneumonia by Duration of Illness When Treatment Was Started

Duration of Illness Before Treatment, Days	No. of Patients Treated			
	Chlortetracycline	Chloramphenicol *	Oxytetracycline *	Penicillin
1-2	10 (19%)	6 (20%)	5 (20%)	10 (25%)
3-4	23 (44%)	10 (33%)	11 (46%)	16 (40%)
5-6	12 (23%)	6 (20%)	4 (17%)	6 (15%)
7 or more.....	7 (14%)	8 (27%)	4 (17%)	8 (20%)
Total.....	52 (100%)	30 (100%)	24 (100%)	40 (100%)

* Data on 2 patients treated with chlortetracycline and 1 treated with chloramphenicol were regarded as inadequate for accurate dating of onset, and these patients are omitted from this table.

Laboratory Procedures.—Routine procedures included white blood cell counts and pharyngeal or sputum cultures. Cold hemagglutination tests were done on a large proportion of patients. Serum specimens were collected soon after admission to the hospital, and two weeks or more after onset, for serologic tests. Complement-fixation tests for the influenza viruses A and B were performed with these serum pairs.

Considerations in Analysis of Results.—In attempting to compare the results in the different groups of patients, consideration was given to several types of criteria, such as the time that elapsed before symptomatic improvement was noted, evidence of clearing of pulmonary infiltrations, and the time required for the patient's temperature to fall. The desirability of using all approaches was obvious, but the two former methods defied objective evaluation. Consequently, the analysis that follows is based on the course of the patient's temperature following the commencement of treatment. Two intervals were determined, namely, (1) the number of hours that elapsed before the oral temperature reached 100 F and (2) the number of hours before a "sustained drop" in temperature was noted. This "drop" was a fall in temperature of 2 degrees Fahrenheit after which the temperature did not exceed the lower reading. With very few exceptions, this drop was accompanied by symptomatic improvement and was followed by prompt clinical recovery.

Method of Deciding Drug to Use.—In the initial phases of the study patients were given one of the four drugs on an alternating system, based on the time of their admission to the hospital. During January a sharp increase in the number of patients admitted to the hospital resulted in a temporary depletion of the supply of chloramphenicol and oxytetracycline and during this period only chlortetracycline was used. Toward the end of this period chlortetracycline and penicillin were used on an alternating basis. When supplies of all drugs were obtained, a system of alternation was resumed and con-

tinued until the end of the study. The numbers of patients who received treatment with each drug are, for these reasons, unequal. The inequality in size of the treatment groups is also due in part to removal from consideration here of patients subsequently shown to have had an influenzal infection. All are included in the following analysis because it is thought that the inclusion of larger numbers outweighs the admitted risk of comparing groups that were not strictly alternated. Also, the methods of analysis that were followed tend in large measure to minimize differences that may have arisen from the unavoidable deviation from a system of absolute alternation.

OBSERVATIONS AND RESULTS

Comparability of Groups Treated with Different Drugs.

—In order to determine whether or not the groups of patients treated with the four drugs were similar, data of two types were analyzed. The first of these was the duration of illness at the time when treatment was started. The data obtained are shown in table 1. In all groups, treatment of the majority of patients was begun within four days of the onset of illness. The proportions of patients treated after the fourth day of illness did not differ greatly. In general the data do not indicate that the stage of illness at which treatment was started in the penicillin-treated group was earlier than the stage at which other drugs were started.

The second type of data was the height of the patient's temperature at the time when treatment was started. Because a spiking type of temperature curve was frequently observed, it was considered advisable to utilize the highest temperature recorded within 24 hours before or after treatment was begun rather than the reading taken precisely at the time when treatment was started. Data showing the distribution of patients by maximal temperature reading during this interval are presented in table 2. Again the differences between the four groups are not large. The data show that the proportion of patients with maximal temperature readings in the lowest range was somewhat larger in the penicillin-treated group and that the proportion of patients with temperatures of

TABLE 2.—Distribution of Patients by Maximum Temperature During Twenty-four Hour Period Before Treatment Was Started

Maximum Temperature, F	No. of Patients Treated			
	Chlortetracycline	Chloramphenicol	Oxytetracycline	Penicillin
100-101.8	15 (28%)	6 (19%)	5 (21%)	15 (38%)
102-102.8	16 (30%)	11 (36%)	9 (37%)	13 (33%)
103-103.8	14 (26%)	11 (36%)	6 (25%)	7 (17%)
104 or more.....	9 (16%)	3 (9%)	4 (17%)	5 (12%)
Total.....	54 (100%)	31 (100%)	24 (100%)	40 (100%)

103 F or more was smaller in this group than in those treated with chlortetracycline, chloramphenicol, or oxytetracycline.

We are fully aware of the fact that data of this sort do not establish the fact that the four groups are strictly comparable. We interpret the findings as indicating that the study was not grossly biased against the penicillin-treated (control) group because of lack of balance with respect to the two factors that have been discussed.

Fall of Temperature to 100 F within 48 Hours.—Data showing the proportion of persons treated with each drug whose temperature fell to 100 F within 48 hours after treatment was started are presented in table 3. It will be noted that, when all patients are considered, a temperature drop of this order was observed in the great majority of patients treated with chloramphenicol, oxytetracycline, and chlortetracycline. Attention is also called to the fact that one-half of the patients treated with penicillin behaved in a similar fashion. This proportion is decidedly lower than that observed in any other group; the difference from the other groups is statistically significant ($X^2 = 7.17$; $N = 1$; $P = < 0.01$).

In order to obtain further information on this point, the patients were divided into three groups on the basis of their maximum temperature at the time when treatment was begun. This afforded a breakdown that correlated to a degree with the severity of the illness. It was observed that, among patients whose maximum temperature was less than 102 F, all those treated with chlortetracycline, chloramphenicol, or oxytetracycline showed, with one exception, a drop in temperature to 100 F within 48 hours (table 3). It should be noted, however, that 13 of 15 patients treated with penicillin

TABLE 3.—Proportion of Patients in Each Therapy Group Whose Temperature Fell to 100 F Within Forty-eight Hours After Treatment Was Started

Maximum Temperature, F	Proportion with Temperature Drop During Treatment			
	Chlortetracycline	Chloramphenicol	Oxytetracycline	Penicillin
Less than 102...	14/15* (93%)	6/6 (100%)	5/5 (100%)	13/15 (87%)
102-102.8	15/16 (94%)	11/11 (100%)	9/9 (100%)	8/13 (62%)
103 or more.....	15/23 (65%)	12/14 (86%)	6/10 (60%)	0/12 (0%)
All patients	45/54 (83%)	29/31 (94%)	20/24 (83%)	21/40 (53%)

* Denominator = no. of patients in temperature-range category; numerator = no. of patients with temperature drop to 100 F.

also showed a fall in temperature of like degree. Among patients whose maximum temperature readings fell between 102 and 102.8 F, all but one of those treated with the three newer antibiotics showed a similar drop in temperature within 48 hours. Again, however, a majority of those treated with penicillin, namely, 8 of 13, behaved in the same way. It was apparent, therefore, that patients in these categories were of little value in bringing out differences in the effectiveness of the drugs and that the differences observed in the crude figures must be attributed largely to those patients whose maximum temperature came within the higher ranges.

Attention was, accordingly, turned to those patients whose maximum temperature exceeded 103 F. Here the difference between the control group and the other groups was sharp. It will be noted that none of 12 penicillin-treated patients showed a temperature drop to 100 F within 48 hours. With each of the other drugs over half of the patients showed a temperature fall of this order. The highest proportion (12 of 14) behaving in this manner was observed in the chloramphenicol-treated group. The corresponding proportions were 15 of 23 in the chlortetracycline-treated group and 6 of 10 in the oxytetracycline-treated group.

Sustained Drop of Temperature within 24 and 48 Hours.—The criteria set up in defining the term "sustained drop" of temperature virtually excluded patients

whose temperature failed to reach 102 F, and for this reason the discussion is limited to patients whose temperature exceeded this figure. Data are presented in table 4. When all patients whose maximum temperature exceeded 102 F were considered, there was again a difference between the penicillin-treated group and those treated with other drugs. The difference was sharper

TABLE 4.—Proportion of Patients in Each Therapy Group in Whom a Sustained Drop in Temperature Was Observed Within Twenty-Four or Forty-Eight Hours

Maximum Temperature, F	Sustained Drop Within	Proportion with Sustained Drop			
		Chlortetracycline	Chloramphenicol	Oxytetracycline	Penicillin
102-102.8	24 hours	7/16 (44%)	8/11 (73%)	6/9 (67%)	5/13 (38%)
	48 hours	14/16 (88%)	11/11 (100%)	8/9 (89%)	7/13 (54%)
103 or more	24 hours	13/23 (57%)	11/14 (79%)	8/10 (80%)	0/12 (0%)
	48 hours	18/23 (78%)	13/14 (93%)	8/10 (80%)	2/12 (17%)

in those patients treated with chloramphenicol or oxytetracycline than in those treated with chlortetracycline.

When the breakdown was limited to those patients whose maximum temperature was 103 F or more, the contrast between the penicillin-treated and other groups was considerably greater. At 24 hours none of the former had shown a sustained drop of temperature, whereas the majority of patients in the other groups had shown such a drop. At 48 hours only 2 of 12 penicillin-treated patients had shown a sustained temperature drop, while in the other groups the proportion of patients behaving in this way was 18 of 23 in the chlortetracycline-treated group; 8 of 10 in the oxytetracycline-treated group; and 13 of 14 in the chloramphenicol-treated group.

Comment on Stages of Disease when Treatment was Started.—It was considered of interest to determine whether control and treated groups differed according to the duration of illness when treatment was begun. The patients were so heavily concentrated in the groups whose illness was four days or less in duration that the numbers in the groups of duration greater than this are rather small. Even so, it may be noted that differences between penicillin-treated and other groups in the proportion of patients whose temperature fell promptly was greatest when the illness was shortest and was least when the illness was of five days' duration or more. Data illustrating this trend are presented in table 5, which shows that so large a proportion of the control group improved rapidly that differences could not be brought

TABLE 5.—Proportion of Patients in Each Group with Sustained Drop in Temperature Within Forty-eight Hours by Duration of Disease When Treatment Was Started

Duration of Illness Prior to Therapy, Days	Proportion with Sustained Drop			
	Chlortetracycline	Chloramphenicol	Oxytetracycline	Penicillin
1-2	6/8 (75%)	3/4 (75%)	4/4 (100%)	2/7 (29%)
3-4	16/18 (89%)	8/8 (100%)	6/8 (75%)	5/12 (42%)
5 or more.....	10/13 (77%)	13/13 (100%)	6/7 (86%)	4/6 (67%)

out. This further emphasizes the difficulty of evaluation of therapy in primary atypical pneumonia in a population such as this, where even the untreated disease tends to be of relatively short duration.

Unsuccessful Treatment with Penicillin and Subsequent Treatment with Other Antibiotics.—It has already been noted that, when patients in the penicillin group

appeared to show no improvement after 48 hours or more, penicillin therapy was discontinued and one of the other antibiotics was substituted. In the discussion thus far, these patients have been considered only with respect to their behavior while they were receiving penicillin, for a therapeutic response to the second antibiotic could not fairly be claimed in view of the fact that the duration of illness was greater when treatment was begun. It is, however, of interest to note that, in eight patients in whom such a shift of treatment was considered advisable, there was in every instance a sustained drop in temperature within 48 hours and in only one instance did more than 24 hours elapse before the temperature had fallen below 100 F. Of these eight patients, three each received chlortetracycline and oxytetracycline and two received chloramphenicol.

Therapeutic Failures.—In view of the difficulty of defining a "therapeutic failure," it is considered advisable simply to record in those instances when the temperature reading had not fallen to 100 F within 48 hours after treatment was started the time that elapsed before the temperatures of patients eventually fell to 100 F. Of nine such patients in the chlortetracycline-treated group, the temperature of four fell to 100 F or less within 72 hours, of an additional three within 96 hours, and in two instances the temperature remained above 100 F for longer periods. Of the two comparable patients in the chloramphenicol-treated group, the temperature of one fell to 100 F within 72 hours. The other patient remained ill with a high temperature for more than a week. The cold hemagglutinin titer of this patient rose from less than 1:4 to 1:512. In the oxytetracycline-treated group all of the four patients whose temperature had not fallen to 100 F within 48 hours showed a drop to that level within 72 hours.

In summary, there were three unqualified therapeutic failures among the 109 patients who were treated with chlortetracycline, chloramphenicol, or oxytetracycline. In an additional four patients, between 72 and 96 hours elapsed before the temperature fell to 100 F. The eight patients whose temperature fell to 100 F between 48 and 72 hours after treatment was started might be classified either as therapeutic failures or as patients with a slow response to the antibiotic.

COMMENT

Comparison of the febrile course in groups of patients who received chlortetracycline, chloramphenicol, oxytetracycline, or penicillin brought out the fact that there was a difference in favor of the first three drugs as compared to the latter. When all patients were considered, this difference was not sufficiently sharp to conclude the argument regarding the effectiveness of these three newer drugs. The fact that the difference was not sharp resulted not from a lack of effectiveness of chlortetracycline, chloramphenicol, or oxytetracycline but rather from the fact that about one-half of the patients treated with penicillin showed a prompt drop in temperature.

Several facts of interest became apparent when patients were divided into groups according to their temperature when treatment was started. This analysis

brought out the fact that in patients whose maximum temperature failed to reach 102 F there was no significant difference between the four groups. Virtually all patients treated with the newer antibiotics showed a prompt fall in temperature, but 13 of 15 patients treated with the control drug showed the same response. It was therefore clear that, with this type of standard, a satisfactory test could not be made in patients whose maximum temperature was in this range because prompt recovery could be expected to occur in most persons with or without treatment. Inclusion of these patients, furthermore, tended to obscure the results of the comparison because of their diluting effect. Attention was therefore focused on those patients whose temperature exceeded 102 F.

When the patients' temperatures prior to treatment were in the highest ranges, the proportion of persons whose temperature dropped promptly following initiation of treatment with the three newer antibiotics was greater than that observed among patients who were given penicillin. Differences were brought out most sharply in those patients whose peak temperature was 103 F or more. It was postulated that, if any or all of these drugs were effective, a considerable proportion of patients should meet one or both of the following exacting criteria: 1. Their temperatures should fall to 100 F within 48 hours. 2. Their temperatures should show a "sustained drop" within 24 hours. None of 12 patients treated with penicillin met either of these criteria. In contrast, both criteria were met by the majority of patients treated with chloramphenicol, oxytetracycline, and chlortetracycline.

Further data supporting the effectiveness of these drugs are provided from the analysis of the relationship of the duration of illness and temperature response. It appeared that with the newer antibiotics a prompt temperature drop occurred regardless of the duration of illness, while in the penicillin-treated group a prompt fall in temperature was likely to occur only when the illness was of five days' duration or more.

It may appear that this is an excessively involved procedure for establishing the therapeutic effectiveness of these three antibiotics. The study brings out, however, the difficulty of conducting a definitive test in the chemotherapy of primary atypical pneumonia. The difficulty arises from the fact that, in a population of the type studied here, the proportion of persons who will recover soon after hospitalization is so large, regardless of the type of therapy, that clear-cut differences between specific drugs and a control preparation are not readily demonstrated. It is only in those patients whose illness is severer that a truly sharp difference can be shown. Patients of this sort make up a relatively small proportion of all patients with primary atypical pneumonia. Attention is called to the fact that it is in this type of patient that effective treatment is really needed.

Documentation of our impression that the fall in temperature was almost always associated with clinical recovery is not possible with the data at hand. Certain points, however, should be considered before one accepts the argument that all that has been demonstrated here is an antipyretic effect and that the underlying disease process continues unchanged.⁴ In many diseases

4. Rammelkamp, C. H.: Personal communication to the authors. Dingle, J. H.: Personal communication to the authors.

fever continues unabated despite the administration of chlortetracycline. One might cite other reports from this project dealing with the use of antibiotics in influenza⁵ and other acute febrile respiratory infections.⁶ In none of these studies was a significant difference noted between the temperature course of patients treated with chlortetracycline and those receiving penicillin or no chemotherapy. Other examples might be quoted from the extensive literature on antibiotic therapy. The experimental evidence reported on this point⁷ cannot yet be applied to the action of chlortetracycline in man. It would seem, therefore, that the burden of proof still lies with those who claim that the effect of chlortetracycline in primary atypical pneumonia is an antipyretic rather than a specific therapeutic one. Finally, evidence should be provided that this "antipyretic" effect is not peculiar to chlortetracycline but is also shared with chloramphenicol and oxytetracycline.

The data obtained pertaining to the relative effectiveness of the three drugs, chlortetracycline, chloramphenicol, and oxytetracycline, are not regarded as adequate for valid comparison. While the proportion of patients whose temperature fell promptly was higher in the chloramphenicol-treated group than in the other groups, it should be noted that a priming dose was used with this drug but not with the others. The more rapid fall in temperature might well be attributed to this rather than to a greater therapeutic effectiveness. Alternative meth-

ods of administering the other drugs or increases in the initial dose of the drugs might have equalized these differences.

SUMMARY

The proportion of patients with primary atypical pneumonia whose temperature fell promptly following treatment with chlortetracycline (Aureomycin), chloramphenicol (Chloromycetin) or oxytetracycline (Terramycin) differed from that observed in a control group treated with penicillin. The difference was negligible in patients whose temperature did not exceed 102 F, because virtually all patients in the control group recovered promptly. In patients whose temperature was 103 F or higher there was a decided difference in favor of chlortetracycline, chloramphenicol, and oxytetracycline over the control drug. The results provide further evidence that chlortetracycline is an effective drug in primary atypical pneumonia and suggest that chloramphenicol and oxytetracycline are at least equally effective.

ETIOLOGY AND MANAGEMENT OF HYPOFIBRINOGENEMIA OF PREGNANCY

C. Paul Hodgkinson, M.D., R. R. Margulis, M.D.

and

J. H. Luzadre, M.D., Detroit

Incoagulable blood as the result of hypofibrinogenemia is an obstetric syndrome of unusual clinical significance. Death from unmanageable hemorrhage may be the penalty. Prompt recognition of the condition and institution of appropriate therapy are obligations of the obstetrician. Hypofibrinogenemia is known to occur superimposed upon two complications of pregnancy. The first and most widely recognized complication is abruptio placentae. The second is prolonged retention of a dead fetus in an Rh-isosensitized mother. Incoagulable blood from a deficiency in circulating fibrinogen is the outstanding pathological characteristic common to both conditions. Detailed analysis of cases discloses possible differences in causes and clinical manifestations.

ABRUPTIO PLACENTAE TYPE

CASE 1.—A 26-year-old woman, para 1, gravida 2, was admitted to Henry Ford Hospital at 12:30 a. m., Dec. 4, 1952, with toxemia and clinical symptoms suggestive of abruptio placentae. Labor had begun at 9:30 p. m. on Dec. 3. Two hours after the patient was admitted, bleeding from the gums, vagina, and intestinal tract was noted. In a coagulation test, no clot was formed (Lee-White method); the fibrinogen content of the blood was zero (Howe method), and the platelet count was 50,000 per cu. mm. (Rees-Ecker method). At 3:50 a. m., a transfusion of 500 cc. of whole blood was given. At 3:55 a stillborn infant showing no maceration was delivered. The placenta showed evidence of two-thirds separation. Approximately 700 cc. of

blood was lost in postpartum hemorrhage. By 4:50, the excessive bleeding was under control. The prothrombin time was 30% of normal (Quick method); the hemoglobin was 10.7 gm. per 100 cc. (Sheard-Sanford photometer); the fibrinogen was 78.4 mg. per 100 cc., and the platelet count was 99,500. At 8:20 a. m. the coagulation time was three minutes. Clot retraction was poor. The fibrinogen level was 156 mg., and the platelet count was 81,900. The Rumpel-Leede phenomenon did not appear. At 9:00 p. m. that evening, the patient appeared disoriented, and nuchal rigidity was noted. The spinal fluid was bloody, and the pressure was increased. At 8:00 a. m., the next morning (Dec. 5), the patient's state of consciousness improved, and her reflexes were hyperactive. The coagulation time was 6.5 minutes, the prothrombin time was 100% of normal; fibrinogen was 131 mg.; hemoglobin was 8.4 gm., and the platelet count was 104,000. A transfusion of 500 cc. of whole blood was given. During the remainder of her hospital stay the patient showed gradual improvement. She was discharged Dec. 22. At no time was clot lysis evident in this patient.

MACERATED STILLBORN TYPE

CASE 2.—A 39-year-old woman was observed for her fourth pregnancy. Her first two pregnancies resulted in delivery of live infants. Her third pregnancy terminated in delivery of a stillborn infant. Her blood group was O, Rh negative, and her husband's was Rh positive.

From the Department of Gynecology and Obstetrics, Henry Ford Hospital.

Read before the Section on Obstetrics and Gynecology at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

The last menstrual period had been Dec. 29, 1946, and the expected date of confinement was Oct. 5, 1947. During the fifth month of gestation fetal death was diagnosed. After several unsuccessful attempts on our part to induce labor with oxytocin (Pitocin), labor began spontaneously at approximately seven months' gestation on July 18, 1947. Labor was of poor quality, and oxytocin was used. After 9 hours and 43 minutes of active labor, she was delivered of a macerated stillborn female infant. The placenta and membranes were degenerated. Bleeding after delivery was profuse, and the blood failed to clot. The uterus was packed without avail. A total of 4,000 cc. of whole blood and 1,500 cc. of plasma was administered over a six hour period. The patient died on the fourth postoperative day from lower nephron nephrosis. Autopsy revealed no evidence of abruptio placentae. The fetus was badly macerated, and the placenta was degenerated.

In 1947, we were not alert to the possibility of hypofibrinogenemia in this type of case. Rh antibody titers were not performed; however, the pregnancy history, along with the known fact that the patient was Rh negative and her husband Rh positive, lends support to the belief that this patient was probably Rh isoimmunized and intrauterine fetal death was due to erythroblastosis fetalis.

CASE 3.—A 26-year-old white woman, para 1, gravida 3, was admitted to the Henry Ford Hospital obstetric service at approximately seven months' gestation. The fetus had been dead eight weeks. Her blood group was O, Rh negative (cde), and her husband was Rh positive (CDE). On Sept. 25, 1952, the indirect Coombs test was strongly positive and the Rh antibody titer 1:64 in albumin. One week prior to admission, she noticed bleeding from her gums. This increased in amount until delivery. The history was significant in that the patient had received a transfusion of her father's blood at the age of eight. Her first pregnancy, in 1951, terminated in delivery of a full-term infant that expired within the first 24 hours from pathologically proved erythroblastosis fetalis.

On Nov. 19, 1952, the patient was admitted to the hospital. She was having mild uterine contractions lasting for 30 seconds at intervals of 7 to 10 minutes. There was bleeding from the gums. The coagulation time was nine minutes and the bleeding time was four and one-half minutes (Duke method). The platelet count was 156,000 per cubic millimeter. At 1:50 p. m. spontaneous delivery occurred. The badly macerated fetus was contained in a degenerated ovular sac with an attached degenerated placenta. There was profuse bleeding from the gums. At 2:03 p. m. the uterus was firmly contracted. Vaginal bleeding, consisting only of liquid blood, was profuse and continuous. The blood fibrinogen level was zero; the platelet count was 48,000, and the bleeding time was five minutes. Ten cc. of calcium gluconate (10%) was given intravenously. At 2:17 the fibrinogen level was 58.7 mg. per 100 cc., and the prothrombin time was 56% of normal. A soft, spongy clot formed in the test tube in 17 minutes and lysed completely within 10 minutes. At 2:30, a clot formed in 25 minutes and lysed in 10 minutes. The clot retraction was zero. The fibrinogen level was 74.6 mg. At 2:40, 500 cc. of fresh blood was given, and at 2:50, 50 mg. of protamine sulfate was given intravenously. Another transfusion of 500 cc. of blood with 10 mg. of corticotropin was given at 3:40. At this time, 25 mg. of corticotropin was administered intramuscularly. At 4:00, clots appeared in the vaginal blood, and the bleeding from the gums ceased abruptly. The fibrinogen level was 87.5 mg. The coagulation time was 10 minutes. The clot was firmer, showed some retraction, and lysed in 20 minutes. The platelet count was 82,000, and the Ac-globulin ratio (Ware and Seegers method) was three units, although some loss of Ac-globulin may have occurred because conditions for the collection of the blood were not ideal. The prothrombin time in the two stage test (method of Warner, Brinkhous, and Smith) was 276 units. At 4:55, the clotting time was 10 minutes, and clot retraction was fair. The clot was partially lysed in 30 minutes and was 75% lysed in 24 hours. The fibrinogen was 110 mg.; prothrombin time was 100%, and

protamine titration (method of Allen and others) was within normal limits. At 6:00 p. m. the bleeding from gums and vagina had ceased, the fibrinogen was 200 mg., the prothrombin time was 100% (260 units by the two stage method) and the Ac-globulin was 10 units. When the patient was discharged from the hospital seven days after delivery, the platelet count was 256,000 and fibrinogen 210 mg.

MACERATED STILLBORN TYPE—CONTROL

CASE 4.—A 25-year-old white woman was followed during her fourth pregnancy. The first pregnancy terminated in delivery of a normal female infant. The second pregnancy terminated at eight months with delivery of a 2 lb. (906 gm.) infant that failed to survive. The third pregnancy, in 1951, resulted in delivery at 28 weeks of a stillborn infant. Death was ascribed to Rh incompatibility. The Rh antibody titer rose to 1:1,056 prior to intrauterine fetal death. The patient's blood was Rh negative (cde) and her husband's was Rh positive (CDE). On Aug. 20, 1952, the Rh antibody titer was reported negative.

Her expected date of confinement was May 25, 1953. The indirect Coombs' test was positive Oct. 21, 1952. On March 5, 1953, the Rh antibody titer was 1:64 in albumin and negative in saline solution. Pregnancy continued uneventfully until the latter part of January, 1953, when the diagnosis of intrauterine fetal death was made. The patient was observed for evidence of hypofibrinogenemia during the interval between fetal death and delivery. Blood fibrinogen levels, prothrombin levels, platelet counts, and clotting times obtained at frequent intervals were within normal limits. On March 27, 1953, the patient delivered a stillborn male infant weighing 600 gm. and showing mild evidence of maceration and liquefaction. The membranes and placenta appeared viable. No excessive bleeding was encountered at any time. The patient's postpartum course was uneventful, and she was discharged from the hospital on April 2, 1953.

Hypofibrinogenemia binds these two obstetric complications for common consideration. Variations in the type of onset, precipitating underlying pathological conditions, and significant laboratory differences suggest problems of theoretical and clinical interest.

Clinical observation¹ has shown wide variations in the time of onset of hemorrhage from hypofibrinogenemia. In the abruptio placentae type, fibrinogen depletion is coincident with placental separation. The macerated fetus type of hemorrhage is gradual in onset. Hemorrhagic manifestations may be evident days before the onset of labor, suggesting a gradual and prolonged loss of circulating fibrinogen.

Abrupt and extensive separation of the placenta, usually with evidence suggesting hemorrhagic infiltration of the uterus, is a constant factor in the abruptio placentae type. In the macerated stillborn type, placental separation is absent. The association of maternal Rh isosensitization, spontaneous death of fetus in utero, long intrauterine retention of a dead fetus, and delivery of a macerated infant have been commonly observed in the macerated stillborn type of hypofibrinogenemia.

Common to both types are depression of plasma fibrinogen, Ac-globulin, prothrombin, and probably platelets. Coagulation time is prolonged; bleeding time is not significantly altered; clot retraction is poor; clot formation is pathological, and blood calcium is undisturbed. The major laboratory difference between the two types lies in fibrinolysis of the clot. In the macerated stillborn type, fibrinolysis of the clot formed in a test tube is a prominent feature apparent to all observers who have reported on this syndrome. In the abruptio placentae type, fibrinolysis of the clot has been inconsistently reported.

E.; Reid, D. E.; Roby, C. C., and Diamond, L. K.: Coagulation Defects with Intrauterine Death from Rh Isosensitization, *ibid.* 60: 1015-1022 (Nov.) 1950.

CAUSES

Abruptio Placentae Type.—Experimentally reproduced and largely clinically accepted are the observations of Schneider,² Page,³ and others,⁴ that hypofibrinogenemia occurs as the result of intravascularly disseminated coagulation. Schneider has shown that, possibly through rupture of the basal decidual plate, the maternal circulation is flooded with decidual and placental extracts rich in thromboplastin. Massive fibrinogen depletion occurs as the result of the conversion of fibrinogen to fibrin. Through the use of placental thromboplastin extract labeled with radioactive iodine, Page⁵ demonstrated that the material is concentrated in the liver, lungs, and spleen.

Macerated Stillborn Type.—The sequence of events leading to fibrinogen depletion in an Rh-isosensitized patient after prolonged retention of a macerated infant is not clear cut. It would seem that absorption of intra-uterine material into the maternal circulation is necessary for disappearance of maternal circulating fibrinogen. In the absence of abruptio placentae, transgression of the decidual barrier could occur through absorption of intraovular fluid after autolytic degeneration of the placenta and membranes. This mechanism has been postulated for amniotic fluid embolism.⁶ That obstetrically recognized placental separation is not necessary for the development of hypofibrinogenemia was proved by examination of the uterus and placenta of the patient in case 2. The importance of autolysis and degeneration of the placenta and membranes in the development of hypofibrinogenemia was suggested from comparison of cases 3 and 4. Violation of the placenta-membrane barrier through the process of autolysis and degeneration can explain why the dead fetus type of hypofibrinogenemia demonstrates gradual onset of hemorrhagic manifestations. Absorption of amniotic fluid rich in products of fetal degeneration and autolysis, and possibly thromboplastin, could possibly support the fibrinogen-fibrin conversion hypothesis.

The thromboplastin absorption does not explain why the macerated stillborn type of hypofibrinogenemia occurs in Rh-isosensitized patients and why fibrinolysis is such a prominent feature in this syndrome. The unique relationship of maternal Rh isosensitization and retention of a dead fetus is a common observation in all cases reported. Does this set of circumstances favor the development of some antibody toxic to fibrinogen during the period from death to expulsion of the fetus, which is presumably Rh positive? Stefanini and others⁷ recently described an antibody type of coagulation defect occurring in hemophiliacs receiving transfusions and in pregnant women near term, especially when there is Rh incompatibility between mother and child. The administration of cortisone was recommended for this type of coagulation defect. Whether there is any relationship of the macerated stillborn type of hypofibrinogenemia to the defect of coagulation described by Stefanini has to be established.

Maternal absorption of intraovular fluid, rich in products of autolysis, is another factor to be considered. Innerfield,⁸ working with rabbits and dogs, noted that trypsin administered intravenously caused depression of the protein constituents of the clotting mechanism.

Fibrinogen was reduced to quantities too low to measure, prothrombin was reduced, and fibrinolysis increased. Innerfield extended his studies to humans and noted similar reduction in fibrinogen and antithrombin levels. Using dogs, we have confirmed Innerfield's observations.

The maternal absorption of amniotic fluid, possibly high in proteolytic enzymes or enzyme activators as indicated by the degree of autolysis of the delivered fetus, placenta, and membranes, is an etiological theory worthy of consideration. Proteolytic assays were performed on normal amniotic fluid with the use of two substrates, gelatin and human plasma clot. These methods failed to demonstrate any evidence of proteolysis. The amniotic fluid of the patient in case 4, in whom hypofibrinogenemia failed to develop, was also negative for proteolysis. Unfortunately, the patient in case 3 was not tested. As reported by others,⁹ the influence of naturally occurring fibrinolysins could also account for the lytic action observed in the macerated stillborn type of hypofibrinogenemia. In a study conducted over the past several months, fibrinolysis during pregnancy and delivery has been investigated. Our studies leave no doubt that, in normal pregnancy, delivery is followed by increased fibrinolysis. The importance of naturally circulating fibrinolysins in the macerated stillborn type of hypofibrinogenemia cannot be evaluated at this time.

MANAGEMENT

Efficient management of hemorrhage from hypofibrinogenemia calls for appreciation of the many factors involved. Inadequate knowledge of the precise causes obscures prophylactic treatment. Sufficient clinical experience, nevertheless, demonstrates the value of preparedness when faced by an Rh-isosensitized patient harboring a dead fetus and also by a patient with abruptio placentae. The rapidity with which disintegration of the blood coagulation mechanism occurs in abruptio placentae leaves little time for other than emergency care. The macerated stillborn type permits adequate time for evaluation.

Laboratory evaluation of blood fibrinogen is a standard procedure. Weiner and others stressed the use of a valuable test that can be employed by the obstetrician

for detection of fibrinolysis. Blood is allowed to clot in a glass test tube at 37 C and is observed at intervals for 24 hours. If the clot dissolves, fibrinolysis is present. This is of value in the detection of the macerated stillborn type. A simplified bedside method for plasma fibrinogen determination is described by Schneider.¹⁰

For successful treatment, fibrinogen replacement may be essential. This is best accomplished through natural regeneration, which occurs in a matter of a few hours. During acute depression of fibrinogen, hemorrhage is profuse and fibrinogen replacement is required. As suggested by Weiner and others, this can best be accomplished by intravenous administration of fibrinogen (2,000 to 8,000 mg.) in saline solution. Unfortunately, fibrinogen is not commercially available; moreover, the virus of infectious hepatitis is concentrated in the fibrinogen fraction, making the use of such fibrinogen hazardous. Until preparations of fibrinogen are commercially available, blood transfusions must be depended on for replacement of fibrinogen.

Weiner stated that a single 500 cc. whole blood transfusion could be expected to elevate the blood fibrinogen level about 10%. To replace fibrinogen from an extremely low level to the normal level by blood transfusions is an almost impossible task. Fortunately it is not necessary to restore fibrinogen levels to normal to control hemorrhage. Although the critical level of blood fibrinogen is not precisely known, some information can be obtained from a study of cases 1 and 3. In case 1, clots appeared in the vagina when the blood fibrinogen was reported to be 78.4 mg. per 100 cc., and active bleeding ceased three hours later. It is estimated that the blood fibrinogen ranged near 100 mg. per 100 cc. at that time. In case 3, clots appeared in the vagina and bleeding abruptly ceased when the fibrinogen reached 87.5 mg.

From these observations, we think the critical fibrinogen level may be about 90 mg. (see figure). The rapidity with which fibrinogen is regenerated is a subject of considerable interest. In case 1 fibrinogen was regenerated, with the aid of one 500 cc. blood transfusion, from zero to 78.4 mg. per 100 cc. in 105 minutes. In case 3, a 1,000 cc. blood transfusion was administered along with calcium, protamine sulfate, 100 mg., and corticotropin (ACTH), 35 mg. The fibrinogen level rose from zero to 87.5 mg. per 100 cc. in 130 minutes. In these two cases fibrinogen therapy was necessary for just a little over two hours.

Stefanini and Gendel¹¹ reported on a patient suffering from a coagulation defect characterized by hypofibrinogenemia and increased fibrinolysis that failed to respond to fresh whole blood, fresh lyophilized plasma and serum, purified preparations of thromboplastinogen, prothrombin, and plasma prothrombin conversion factor. Cortisone arrested the bleeding, decreased the fibrinolytic activity, and prolonged the survival time of the various clotting proteins. In case 3, we administered corticotropin. Clots appeared in the vaginal blood 10 minutes after administration of the drug. The value of fresh blood as opposed to bank blood in the treatment of this syndrome is a question of practical value. Fibrinogen, Ac-globulin, and prothrombin will not deteriorate during storage in the blood bank. Blood platelets rapidly deteriorate in storage. For this reason fresh blood would appear to be of more value than platelet-deficient bank blood.

Subjecting a patient suffering from such a coagulation defect to a major operation is hazardous. Unfortunately, for emergency measures, this is sometimes necessary. Rapid evacuation of the uterus is at times necessary in abruptio placentae. The importance of administration of blood or fibrinogen in such instances can hardly be overemphasized. Hysterectomy for uncontrollable postpartum hemorrhage is an accepted emergency procedure. With the diagnosis of critical deterioration of the blood coagulation mechanism, hysterectomy can hardly be considered a measure of therapeutic value. Bleeding will stop with therapeutic elevation of the fibrinogen level. Amniotomy during labor, for release of intraovular fluid, could theoretically reduce maternal absorption. The value of this procedure must await clinical trial. Stimulation of labor with oxytocics, when the membranes are intact, is a procedure of questionable merit. Forceful labor contractions could increase maternal absorption of amniotic fluid. Theoretically, fibrinogenopenia would be increased.

SUMMARY AND CONCLUSIONS

Two obstetric complications leading to hypofibrinogenemia and defective blood coagulation are compared. The abruptio placentae type causes fibrinogen-fibrin conversion as the result of absorption into the maternal circulation of thromboplastin. Symptoms are coincident with placental separation. In the macerated stillborn type the onset of symptoms is gradual and is not dependent on placental separation. Several possible causal factors are discussed. Successful treatment depends on elevation of the blood fibrinogen above the critical level of about 90 mg. per 100 cc. Natural regeneration of fibrinogen is

prompt. Administration of fibrinogen is of proved value, but fibrinogen is not commercially available. Until it is, obstetricians must depend on whole blood transfusions in the treatment of hypofibrinogenemia. Some evidence is presented that corticotropin or cortisone may be of value in the treatment of the macerated stillborn type of hypofibrinogenemia.

Cesarean section, to effect prompt delivery, is at times necessary. Blood should be available in adequate quantities before this procedure is undertaken. Hysterectomy for the treatment of hemorrhage from hypofibrinogenemia is not recommended, as this only adds to the source of hemorrhage.

and

Edward H. Kass, M.D., Ph.D., Boston

The chemical structures of chlortetracycline (Aureomycin)¹ and oxytetracycline (Terramycin)² have now been resolved after many months of chemical and biological studies. The close similarity in the chemical structures of these two antibiotics, which was revealed by these studies, had long been suspected on the basis of the almost identical spectrums of their antimicrobial activity and from the almost complete cross resistance between them.³ Common to both of these antibiotics is the following structure:

The name tetracycline has been proposed for this antibiotic. Chlortetracycline differs from oxytetracycline by the presence of one chlorine atom in the former that is absent from the latter and the presence of a hydroxyl group in oxytetracycline that is absent from chlortetracycline. The structures of these two antibiotics are as follows:

The preparation of tetracycline by the catalytic hydrogenation of chlortetracycline, using palladium as a catalyst, was reported recently by workers of both the Lederle Laboratories⁴ and of Chas. Pfizer and Company.⁵ Further observations on the physical and chemical properties of this new antibiotic and the results of laboratory and clinical investigations with tetracycline were described in a group of papers presented on Oct. 28 at an antibiotic symposium sponsored by the Division of Antibiotics of the Food and Drug Administration, Department of Health, Education, and Welfare, in collaboration with the journal *Antibiotics and Chemotherapy*. These papers will be included in detail in the volume of the proceedings of this symposium, which is to be published.

The details of the preparation, the physical and chemical properties, and proof of the structure of tetracycline were presented by Boothe and co-workers.⁶ In a second paper Bohonos and co-workers⁷ compared the anti-

bacterial action of the three tetracyclines in vitro, using three different methods, namely, streak-plate, agar-diffusion, and broth-turbidimetric tests. The three antibiotics were found to have similar patterns of antibacterial action, but they differed markedly in chemical stability. These differences resulted in quantitative variations in their apparent in vitro activities. In the agar diffusion (cup plate) method, at pH 6.0, all three produced larger zones of inhibition than at pH 7.8, but chlortetracycline showed significantly higher activity than the other two agents at the lower pH levels. In the turbidimetric tests, the order of activity of the three analogues changed depending on the time when readings were made; with short incubation periods, chlortetracycline was generally the most active, but when the incubation period was extended, chlortetracycline became less active. However, after extended periods of incubation, cultures from the tubes showing partial inhibition showed the same sensi-

From the Thorndike Memorial Laboratory, second and fourth medical services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

This study was aided by a grant from the United States Public Health Service.

The chlortetracycline (Aureomycin) used in this study was provided by Dr. Stanton M. Hardy, Lederle Laboratories Division, American Cyanamid Company, and the oxytetracycline (Terramycin) by Dr. Gladys L. Hobby, Chas. Pfizer and Company.

tivity as the original ones, indicating that this phenomenon was not the result of induced resistance. When the readings were done at three hours, in a test carried out at pH 7 and using *Micrococcus pyogenes* var. *aureus* (*staphylococcus aureus*), chlortetracycline was much more active than the other two.

The results of studies on the stability of these three analogues were also reported.⁷ At 37 C and pH 8, oxytetracycline was the most stable, but only slightly more than tetracycline, while chlortetracycline was the least stable under these conditions. However, at pH 7, tetracycline was definitely the most stable of the three. After being heated at 100 C for 15 minutes, tetracycline showed the least loss of activity over a wide range of pH, but were more stable at pH 2.5 than at pH 7 or 9.

The results of pharmacological studies of tetracycline in mice, rats, and dogs were presented by Cunningham and his co-workers.⁸ Tetracycline was shown to be relatively nontoxic when given in moderate or large doses intravenously to mice, intraperitoneally to rats, and orally to dogs. No significant changes were observed in dogs after daily intravenous injections of doses of 10 to 30 mg. per kilogram of body weight for 23 days with respect to kidney function, blood clotting, nonprotein nitrogen, blood sugar, and complete blood cell counts. No untoward reactions were seen in dogs receiving 100 mg. per kilogram by mouth twice daily, 5 days a week, over a 12 day period. The tetracycline showed no significant antispasmodic, anticoagulant, cardiovascular, or respiratory effects. The antibiotic was excreted rapidly by the kidney and was found in the urine of rats and dogs after intravenous administration. In dogs, after a single intravenous injection of 500 mg. per kilogram there were appreciable blood levels for at least 24 hours. Tetracycline was readily absorbed from the gastrointestinal tract of the rat and dog. The antibiotic was found to be concentrated in the bile, substantial quantities being detected five hours after a single intravenous injection of 10 mg. per kilogram. Tetracycline was found to cross the blood brain barrier, and an average concentration of 0.56 mcg. per milliliter was found in cerebrospinal fluid five hours after a single intravenous injection of 10 mg. per kilogram in normal dogs.

A comparative evaluation of the three tetracyclines in experimental infections was reported by Kiser and his co-workers.⁹ Their tests were carried out in mice with infections induced by *Streptococcus pyogenes* strain C203, *M. pyogenes* var. *aureus*, *Diplococcus pneumoniae* type 1, *Pasteurella multocida*, *Klebsiella pneumoniae* type B, and *Mycobacterium tuberculosis* var. *hominis*, strain H37Rv, and in chicks infected with *Salmonella gallinarum*. They found little difference in activity among the three antibiotics, except that chlortetracycline was found to be significantly more effective against *Pasteurella* organisms. Oxytetracycline was found to be considerably less active than the other two

in the tests with *K. pneumoniae*, and chlortetracycline was essentially inactive in *Myco. tuberculosis* infection in mice.

Similar observations confirming or extending many of these details, with only minor differences in results, were presented by English and associates.¹⁰ Still another series of observations, which likewise confirm many of these findings, was reported by Minieri and co-workers¹¹ of the Heyden Chemical Corporation; the tetracycline used in the latter studies, however, was reported to have been produced by direct fermentation, using a new strain of organism isolated from a sample of soil obtained from Texas.

The present paper deals primarily with some laboratory observations made at the Thorndike Memorial Laboratory and with some clinical trials conducted on the wards of the Boston City Hospital with tetracycline provided by the Lederle Laboratories, the more recent lots of the antibiotic being furnished under the tradename Achromycin. A brief summary of many of these findings was presented at the antibiotic symposium referred to previously.

MATERIALS USED

The tetracycline was all provided as the hydrochloride in the following forms: sterile crystals in sealed, rubber-capped vials; similar material with sodium glycinate buffer and ascorbic acid added as a preservative, likewise contained in sterile rubber-capped vials; and capsules containing 200 mg. and later 250 mg. each and tablets containing 250 mg. each. Chlortetracycline was also provided as the hydrochloride in similar forms. Oxytetracycline was supplied in similar forms, except that the tablets were prepared with the free base instead of the hydrochloride.

RESULTS OF LABORATORY STUDIES

Stability.—A limited number of observations were carried out to determine the stability of the solutions of the three tetracyclines under conditions in which they may be used in the clinic or in bacteriological laboratories. Standard solutions of the hydrochloride of the three tetracyclines were made up in concentrations of 8 mcg. per milliliter or less in 0.85% sodium chloride, and citrated plasma was obtained from patients under treatment with the three tetracycline analogues. These were tested at various intervals during storage at -25 C, 5 C, and during incubation at 37 C. A strain of *Bacillus cereus* no. 5, originally obtained from Dr. Dornbush of the Lederle Laboratories, was used as the assay organism, and the tests were carried out in brain heart infusion broth (Difco pH 7.2), in part by a serial two-fold dilution test and in part using an arithmetic dilution gradient in the vicinity of the expected end-points. At -25 C (in a mechanical "deep-freeze" unit) solutions of all three analogues retained their activity essentially unaltered for at least six weeks. At 5 C (in a commercial refrigerator) the solutions of chlortetracycline showed appreciable deterioration in antibacterial activity between 24 and 48 hours; oxytetracycline showed moderate deterioration by the end of the first week, while the activity of tetracycline was unaffected in three weeks. Similar results were obtained with citrated plasma from patients being treated with these three agents.

Antibacterial Action.—Simultaneous tests for sensitivity to tetracycline, oxytetracycline, and chlortetracycline were made with 257 recently isolated strains of common pathogenic bacteria. These tests were carried out by streaking the fully grown cultures on agar plates containing serial two-fold dilutions of the antibiotics, horse blood being added to the agar when required for optimum growth of the organisms. The results were read after incubation at 37 C for 24 hours, except in the case of meningococci and gonococci, which were incubated for 48 hours. Sensitivity of the strains was measured in terms of the minimum concentration of antibiotic contained in the agar that completely or almost completely inhibited the growth of the organisms after the stated incubation period and is expressed in micrograms per milliliter. Recently isolated strains were used because of the possible changes in resistance of some organisms resulting from the use of some of these tetracycline analogues in the past few years, as is well illustrated in the case of the staphylococci.¹²

the same as for tetracycline in somewhat less than one-third of the strains; also, less than one-fourth of the strains appeared to be more sensitive to chlortetracycline than to tetracycline and almost one-half of the strains were more resistant or required greater amounts of chlortetracycline than tetracycline to inhibit. This relatively lower activity of chlortetracycline must be attributable, in a large part at least, to the deterioration of the chlortetracycline during the 24 hour or longer incubation period before the results of the tests were read.

For individual species or genera, there appeared to be some differences in the action of the individual agents, although the significance of these differences must await the accumulation of further data with larger numbers of strains. Thus, tetracycline appeared to be the most active of the three analogues against *Escherichia coli*, *Shigella sonnei*, and *Proteus* organisms. Oxytetracycline appeared to be the most active of the three agents against strains of *Pseudomonas*, and chlortetracycline appeared to be the most active against strains of *Enterococcus*,

* Minimum concentration producing complete or marked inhibition after incubation for 24 hours on antibiotic-containing agar, except for meningococci, which were read after incubation for 48 hours.

† Number of strains inhibited by one-half concentration or less (left), same concentration (middle), and two or more times as much (right); superscripts indicate number inhibited by one-quarter or less in left column and by four times or more in the column on the right.

‡ Six of the staphylococcal strains and eight of the enterococci were resistant to 200 meg. per milliliter; the rest were inhibited by 3.1 meg. per milliliter or less.

§ Dr. Sara E. Branham, National Microbiological Institute, supplied most of the strains of meningococci.

The results are summarized in table 1. Both the range of sensitivity for the various genera and species of bacteria and the minimum concentration required to inhibit two-thirds of the strains of each are listed in this table. The comparative sensitivities of the same group of strains to oxytetracycline and chlortetracycline when tested simultaneously and by the same method are shown alongside of the results obtained with tetracycline.

All of the organisms were quite similar in their sensitivity or resistance to the three antibiotics, although a number of individual strains were more sensitive to one or another of them to a degree that was probably significant and beyond the limits of error of the method. When the results of these tests are considered in toto, more than one-half of the strains were equally sensitive to oxytetracycline and to tetracycline; the rest were more or less equally divided between those more sensitive and those more resistant to oxytetracycline, the difference for most strains being within the error of the two-fold dilution method that was employed. In the tests with chlortetracycline, the minimum inhibiting concentrations were

M. pyogenes var. *aureus*, and *Str. viridans*. Chlortetracycline appeared to be inferior to the other two analogues, particularly against the meningococcus and the gonococcus, but in these instances the longer incubation period that was necessary because of the slow growth of these organisms on the mediums used was probably responsible for this apparent difference.

Growth Curves.—Growth curves were carried out with a group A hemolytic *Streptococcus* (*Streptococcus* 98) and with *B. cereus* no. 5, using both pour plates to determine the number of viable organisms and turbidimetric measurement of the density of cultures after various periods of incubation with different concentrations of the antibiotic and various sizes of inoculums. These studies, the details of which will be reported elsewhere, indicated that all three analogues acted in a very similar manner during the first few hours of incubation.

12. Finland, M., and Haight, T. H.: Antibiotic Resistance of Pathogenic Staphylococci: Study of 500 Strains Isolated at Boston City Hospital from October, 1951, to February, 1952, *A. M. A. Arch. Int. Med.* 81: 143-158 (Feb.) 1953.

After 12 hours, however, the deterioration of chlortetracycline was indicated by resumption of growth, and the greater stability of tetracycline was shown by the fact that growth was delayed longer and inhibition was more prolonged and more permanent with the latter agent than with the other two analogues.

Resistance and Cross Resistance.—In the tests for sensitivity previously referred to, organisms that were highly resistant to any one of the agents were always

Fig. 1.—Plasma concentration of tetracycline after a single intravenous injection of 1.0 or 0.5 gm. in isotonic sodium chloride solution or dextrose solution.

resistant in about the same degree to each of the other two. A study was also made to determine specifically whether repeated and prolonged exposure of organisms to one of the three analogues in vitro would result in the development of resistance to other agents as well. Eight strains, including two of *Enterococcus*, two of *M. pyogenes* var. *aureus*, and one each of *K. pneumoniae*, *Esch. coli*, *Aerobacter aerogenes*, and *Str. viridans* were subcultured repeatedly in broth containing increasing concentrations of tetracycline and oxytetracycline. The resistance of these strains generally increased during 11 subcultures from 8-fold to 32-fold against the homologous antibiotic to which the strains were exposed. Increases in resistance to each of the two heterologous analogues to which the organisms had not been exposed developed in every instance, and in most instances the increases were of about the same order of magnitude as against the homologous antibiotic. For some strains, however, the increases in resistance to the heterologous analogues were apparently greater than to the agent to which they had been exposed.

Blood Levels.—Assays for tetracycline activity were made with venous blood of patients who were given single doses expressly for this purpose and in other patients who were under treatment with the new antibiotic. Samples of citrated plasma were assayed by a serial two-fold dilution test in broth using a 10^{-4} dilution of a 12 hour culture of *B. cereus* no. 5 as the test organism. The results were read as the minimum dilution of plasma producing complete inhibition of growth after 18 hours incubation at 37 C, and the concentrations

of antibiotic were determined from this dilution by comparison with parallel assays of standard solutions of the antibiotic carried out at the same time. The results of such assays following single intravenous injections of 1.0 or 0.5 gm. of tetracycline hydrochloride, given as an effusion in 1.0 or 1.5 liters of isotonic sodium chloride solution or of 5% dextrose solution, over a period of two hours, are shown in figure 1. Growth of the test organisms was generally inhibited by dilutions of plasma ranging from 1:16 to 1:512, which are equivalent to concentrations of 1 to 32 mcg. per milliliter respectively. High levels were sustained after such infusions for 12 hours, and in some patients levels ranging from 0.25 to 16 mcg. per milliliter were still present during most of the second 12-hour period.

During therapy with oral doses of 250 mg. or 500 mg. every six hours, peak concentrations were generally not achieved until after the second dose was given, and the levels were only slightly higher on or after the second day of treatment in the patients receiving doses of 500 mg. every six hours (fig. 2). An initial dose of 1.0 gm. by mouth was given to a few of these patients and resulted in somewhat higher levels during the first 12 hours. With the 500 mg. doses, more or less uniform levels were obtained and ranged from 1 to 8 mcg. per milliliter in most patients after the first 12 hours of treatment. Levels of 16 mcg. per milliliter of plasma have been found in several specimens obtained during treatment with this dosage. The dose of 250 mg. every six hours was given chiefly to patients with urinary tract infections, some of whom had impaired renal function. The resulting blood levels were, therefore, more irregular, but generally ranged from 0.25 to 16 mcg. per milliliter throughout several days of continuous treatment. In a few patients, observations made after the last dose

Fig. 2.—Plasma concentration of tetracycline during therapy with 250 mg. given every six hours.

indicated that appreciable concentrations of tetracycline were present in the plasma for 12 hours or longer in most patients.

A carefully controlled experiment was carried out in 12 volunteers, all of whom received single doses of 1.0 gm. of each of the three tetracyclines by mouth in rotation at different times without any of the participants knowing which of the antibiotics they were taking. Details of this experiment will be published elsewhere,

but the results may be summarized here briefly. With all three agents, the peak levels were achieved between four and six hours, and generally ranged from 1 to 4 mcg. per milliliter of plasma. The levels were sustained at or near these peaks in almost every instance for eight hours after administration of each of the agents and, in most of the subjects tested, similar levels were still present in the plasma 12 hours after the dose was taken. The average concentrations of the antibiotics for all of the subjects were highest after the ingestion of tetracycline and lowest after ingestion of oxytetracycline. These comparisons were made on the basis of readings of the assay test after 18 hours of incubation. When the tests were read at 24 hours, the deterioration of chlortetracycline was evident, and by 40 hours, no inhibition could be demonstrated in any of the serums from the subjects who received chlortetracycline. There was only a slight reduction in the concentrations that were inhibitory after these longer incubation times in the plasmas taken after the doses of oxytetracycline, while the levels following ingestion of tetracycline were essentially unchanged. Some of the lower levels obtained following ingestion of oxytetracycline may have been due to the fact that half of the subjects were given this analogue in the form of tablets of the free base; two subjects who received such tablets showed no demonstrable levels in the blood at any time, and the average for the remaining subjects was somewhat lower than in those who received the oxytetracycline in the form of capsules of the hydrochloride.

Urinary Excretion.—Samples of urine obtained at random in patients under treatment with tetracycline showed high concentrations of this agent, ranging from 40 to more than 1,000 mcg. per milliliter. In the controlled experiment on absorption following the ingestion of a single dose of 1 gm., each of the three tetracycline analogues appeared rapidly in the urine so that samples obtained two hours after the dose was taken contained between 20 and 320 mcg. per milliliter. The urine specimens collected between 2 and 12 hours after the dose yielded antibiotic levels ranging from 160 to 640 mcg. per milliliter in most instances, and those obtained in the next 12 hours still showed from 40 to 160 mcg. in most instances and even higher concentrations in some. Total amounts ranging from 9 to 21% of the ingested 1 gm. dose were recovered during the first 12 hours from each of the subjects and with each of the agents, except for two subjects who had received tablets of the free oxytetracycline base; from one of these subjects only 3% and from the others 6% of the administered dose was recovered during the first 12 hours. An additional 4 to 7% of the administered dose was recovered during the second 12 hour period in most instances, but in individual subjects considerably larger amounts were recovered during this period.

Spinal Fluid Levels.—Simultaneous specimens of blood and spinal fluid were obtained from 7 patients without meningitis at varying intervals after single injections of 0.5 to 1.0 gm. of tetracycline given over a two hour period. Tetracycline activity was demonstrated in the spinal fluid in two of these subjects and in concentrations equivalent to $\frac{1}{8}$ and $\frac{1}{32}$ of the simultaneous blood levels, respectively. In the other five, including

two who showed only minimal levels in the plasma, no activity could be demonstrated by the test used. Additional data concerning spinal fluid gradients of tetracycline analogues were presented at the antibiotic symposium by Wood, Kipnis, and Dowling.¹³ They showed that tetracycline was more regularly demonstrated in spinal fluid and at relatively higher concentrations than each of the other two analogues.

CLINICAL TRIAL

From May through October, 1953, 118 patients were treated with tetracycline hydrochloride given in tablets or capsules orally, by intravenous injection, or by both routes. Almost all of these patients were adults on the medical wards of the Boston City Hospital. In general, all patients admitted to the wards on which this study was being conducted and in whom a broad-spectrum antibiotic was indicated or justifiable were treated with

tetracycline alone. Patients who had previously received other antimicrobial agents were excluded unless those agents had definitely failed to control the infection and had already been discontinued for several days.

Dosage.—A summary of the various dosage regimens and the total amounts and duration of therapy used in the patients in this study is given in table 2. About one-half of the patients received oral doses of 500 mg. every six hours; the rest received either 200 or 250 mg. every four or six hours. An initial oral dose of 1.0 gm. was given to a number of the patients on each of the regimens, and some of those who received individual doses of 200 or 250 mg. were given 500 mg. initially. Intravenous doses of tetracycline hydrochloride were given in 0.5 to 1.0 gm. amounts dissolved in 1.0 or 1.5 liters of isotonic sodium chloride solution by slow infusion at intervals of 12 hours or longer; this was the only therapy used in 5 patients, but it was used during the

13. Wood, W. S.; Kipnis, G. P., and Dowling, H. F.: Blood and Cerebrospinal Fluid Gradients of Tetracycline Analogues, to be published.

first day or 2 in 13 additional patients before oral dosage was started. The total amount given intravenously did not exceed 3.0 gm. in any of the patients. The total amount given orally varied from a single dose of 500 mg. (in a "terminal" case) to 52 gm. in 26 days. Most of the patients received between 5 and 15 gm. over a period of 4 to 10 days, and the average total dose was 10.7 gm. in 7.0 days.

* Two of these patients had bacteremia.

† These patients had hepatic coma.

‡ There was one case each of acute gastroenteritis, Sonne dysentery, otitis media, and fever of undetermined origin.

§ Therapy was for prophylaxis in patients with myocardial infarcts in four cases, fever of undetermined origin in two, acute cholecystitis, perineal cellulitis, infected dermatitis, and infectious mononucleosis in one each.

cases are listed in table 3. In a major proportion of the patients, treatment was given for urinary tract infections; the majority of these patients had chronic or recurrent infections complicated by irremediable obstructive lesions or by indwelling catheters. Only a few such patients yielded excellent clinical or bacteriological results, while others were definitely improved; however, nearly one-half of them had mixed infections and most of these patients were not clearly benefited by the tetracycline treat-

ment. In many of them there was temporary improvement associated with disappearance of one or more of original infecting organisms only to be followed by rapid return of bacilluria or pyuria accompanied by the presence of organisms not isolated in the pretreatment cultures. The patients with acute infections of the urinary tract, on the other hand, showed excellent results, both clinical and bacteriological; most of these were infections with *Esch. coli*.

Similar results were obtained in pulmonary infections. The patients with uncomplicated acute pneumonia all responded well; most of these were pneumococcal and some of the others were probably of pneumococcal etiology according to their clinical behavior, although a pneumococcus was not definitely identified. There were two patients with staphylococcal pneumonia who also responded favorably. The patients with chronic bronchopulmonary suppuration, many of them with mixed infections, showed variable but rarely spectacular results; most of these patients were treated during acute exacerbations and had in their sputums a variety of organisms, many of which are not usually considered to be respiratory pathogens (including coliform organisms). Patients in whom *Hemophilus influenzae* predominated in the sputum generally showed definite clinical and bacteriological improvement during treatment.

The patients with acute hemolytic streptococcal pharyngitis showed excellent clinical and bacteriological responses in every instance. Among those with miscellaneous infections there were three patients with staphylococcal bacteremia, one with *A. aerogenes* bacteremia complicating hepatic coma, one with acute gastroenteritis (possibly staphylococcal), a case of Sonne dysentery (due to *S. sonnei*), and one with suppurative otitis media, all of whom showed excellent or good clinical and bacteriological responses. The other patients included some with fevers of unknown etiology, others with myocardial infarcts and congestion in the lung associated with fever, patients with hepatic coma, one with acute cholecystitis, and one with an ulcer around the perineum due to a mixed infection; in these patients the effect of tetracycline was generally indeterminate or nil.

On the whole, it may be said that the therapeutic results with tetracycline in the present study were similar in every respect to those obtained in a recent controlled clinical study, carried out on the same wards, in which the effects of oxytetracycline and chlortetracycline were compared.¹⁴ Obviously, a much more extensive and thoroughly controlled study would be required to detect any possible differences in clinical activity of tetracycline from that of the earlier two analogues.

Untoward Effects.—The most striking and encouraging feature of the clinical trial of tetracycline was the relatively low frequency of toxic effects observed, in contrast to the previous experience with chlortetracycline and especially with oxytetracycline, in similar types of patients, with similar infections, previously treated with comparable or smaller doses and on the same medical wards. All of the untoward effects observed from tetracycline in the present study were limited to symptoms referable to the gastrointestinal tract, but these were distinctly less frequent and less severe than those pre-

¹⁴ Finland, M.; Grigsby, M. E., and Haight, T. H.: Efficacy and Toxicity of Oxytetracycline (Terramycin) and Chlortetracycline (Aureomycin): With Special Reference to the Use of Doses of 250 Milligrams Every 4 or 6 Hours and to the Occurrence of Staphylococcal Diarrheas, A. M. A. Arch. Int. Med. 93: 23 (Jan.) 1954.

vously noted in the comparative study with oxytetracycline and chlortetracycline. In that study, as shown in table 4, diarrhea occurred about twice as frequently in patients treated with oxytetracycline (19%) as in those treated with chlortetracycline (10%). Moreover, staphylococci were present quite regularly as the only or predominant organism in the frequent and watery diarrhea.

* The patients were treated with oxytetracycline and chlortetracycline on the same wards in a controlled study in 1951-1952, reported in detail elsewhere; most of these patients received 250 mg. every four or six hours, but a few were treated with 500 mg. every four or six hours.

† Includes patients with soft bulky stools without diarrhea.

reah stools associated with oxytetracycline therapy, but they occurred in only a small number of the patients during treatment with chlortetracycline.

In the present study, five patients had diarrhea from oral tetracycline therapy; the diarrhea was mild and brief except in one patient in whom it lasted for two days. Moreover, only one had a large number of staphylococci (mixed in this case with a large number of enterococci) in the feces. One other patient had a moderate number of staphylococci in the stools, but other common fecal organisms predominated in the same specimens. Nausea and vomiting were noted in two patients, large bulky stools in one, and a sore, beefy tongue in another. No other toxic effects were observed during tetracycline therapy in this study. Several patients had diarrhea or nausea and vomiting before treatment with tetracycline was started that subsided during the treatment. Diarrhea occurred in one patient following vigorous catharsis, and vomiting in another was attributable to over-digitalization during tetracycline therapy; these episodes necessitated brief interruption of tetracycline therapy, which was later resumed without untoward effects. Most of the toxic effects from oral therapy observed in the present study occurred in patients who received the tetracycline in the form of tablets. Although almost twice as many patients were treated with tetracycline hydrochloride in capsules, only one of them had diarrhea and another experienced a sore, beefy tongue during treatment; all of the remaining gastrointestinal disturbances were experienced by the patients who received tetracycline tablets. The occurrence of untoward effects from each of the various lots of tetracycline hydrochloride that were used in the present study is summarized in table 5.

There were no untoward effects whatever from intravenous infusions of tetracycline hydrochloride in 0.5 to 1.0 gm. amounts in single or multiple doses at 12 to 24 hour intervals, but not exceeding a total of 3.0 gm. in any one patient during this study. All but 5 of these 18 patients who received intravenous tetracycline therapy subsequently received oral therapy.

Many additional patients were given single oral doses of tetracycline hydrochloride in capsule or tablet form in amounts ranging from 0.25 to 1.0 gm. for various studies. No toxic effects were observed in any of these patients. In the control study previously mentioned, when the 12 subjects each received 1 gm. of each of the three analogues in rotation without at any time knowing which they were getting, the differences in the gastrointestinal toxicity from the three antibiotics were clearly discernible. No untoward effects whatever were observed following the ingestion of 1.0 gm. of tetracycline in these 12 subjects, except for one who passed 3 soft bulky stools during one day. On the other hand, with the same dose of oxytetracycline given to the same 12 subjects, either before or after the tetracycline therapy, diarrhea

TABLE 5.—*Untoward Effects of Tetracycline Hydrochloride Therapy*

Lot	Form	Dose, Gm./Day	Number of Patients *	Untoward Effects

F	Intravenous	0.5-2.0	18	None	

* The figures in parentheses are the number of patients who received initial doses intravenously. Only five patients received all of the tetracycline intravenously. Three patients received both lots D and E, 2.0 gm. daily of each, without untoward effects from either.

† One of these patients was receiving large doses of *p*-aminosalicylic acid with isoniazid orally and streptomycin intramuscularly at the same time.

occurred in five and lasted in them from two to five days. Nausea accompanied the diarrhea in one instance and was present in another subject who did not have diarrhea. Flatulence was experienced by one of the subjects who had diarrhea after taking oxytetracycline and by another who was free of any other symptoms. Following the dose of 1 gm. of chlortetracycline, diarrhea was ex-

perienced by two subjects, both of whom had had the same effect following the dose of oxytetracycline that they had taken four days previously; one of them had not entirely recovered from the same symptoms that occurred after the previous dose. Nausea was experienced by two other subjects and bulky stools were noted in two additional ones following the chlortetracycline dose. One of the two persons who experienced nausea from chlortetracycline had received no other antibiotic previously. This experiment therefore confirmed very clearly the relative gastrointestinal toxicity of the three agents; tetracycline was the least toxic, chlortetracycline next, and oxytetracycline produced the greatest incidence of these untoward effects.

SUMMARY AND CONCLUSIONS

The antibacterial activity of tetracycline closely resembles, and in most respects is almost identical with, that of oxytetracycline (Terramycin) and chlortetracycline (Aureomycin). There is essentially complete cross resistance among the three tetracycline analogues in vitro. Chlortetracycline is considerably less stable than either of the other two analogues when kept in solutions, particularly in an alkaline medium. Satisfactory blood levels are sustained during treatment with oral doses of 250 mg. or 500 mg. of tetracycline hydrochloride every six hours, and high concentrations are maintained in the urine during treatment with such doses. After single oral doses of 1 gm., the concentrations of antibiotic obtained in the plasma appeared to be somewhat higher with tetracycline than with the other two analogues.

A clinical trial was carried out in 118 patients treated with tetracycline, most of them for infections of the

urinary or respiratory tract. The clinical and bacteriological effects of such treatment appeared to be similar to those obtained in a recent study with oxytetracycline or chlortetracycline in similar cases. The major clinical difference between tetracycline and the other two analogues is the distinctly lower incidence of untoward gastrointestinal symptoms from tetracycline. These results suggest that further clinical trials with tetracycline are warranted.

ADDENDUM

After this paper was submitted, 61 additional patients were treated with tetracycline; 38 received capsules, 22 were given tablets, and one received all of the antibiotic intravenously. The oral dose was 250 mg. every four or six hours in 24 patients and 500 mg. every six hours in 36; 5 of the latter group received initial doses intravenously. Excellent clinical and bacteriological results attributable to tetracycline were obtained in 28 patients (including one with meningococcic meningitis who received no other antimicrobial therapy); clinical and/or bacteriological improvement resulted from treatment in 20 patients; the results were indeterminate in 11 and there was no benefit from tetracycline in the remaining 2. Of those who received capsules, one had diarrhea briefly and this was controlled with paregoric while treatment continued, and one patient complained of flatulence only. Among those treated with tablets one had nausea and vomiting on the fifth day and two others, both of whom had marked azotemia, had some vomiting before tetracycline was started and this continued intermittently during treatment.

THE TONSIL AND ADENOID QUESTION AS SEEN BY THE INTERNIST

Theodore L. Badger, M.D., Boston

Of how many operations can it be truthfully said that they are "neither dreadful in the doing nor melancholy in the event"? This unique pronouncement, which was intended to popularize the removal of tonsils by ligature, is found in the "Critical Inquiry into the Present State of Surgery" by Samuel Sharp, surgeon to Guy's Hospital, 1733 to 1757. Sharp's work is cited in an article by Mollison.¹

The tonsils, being easily visible and readily accessible, must have been among the very first of our internal organs to be removed by the surgeon's knife. Wise,² in his "Review of the History of Medicine," speaks of the Asiatic Indians, who were highly skilled in medicine 1,000 years B.C., or 460 years before Hippocrates. These Asiatics

removed troublesome tonsils saying, "They are to be seized between the blades of a forcep and drawn forward, and with a semicircular knife the third of the swelled part is to be removed. . . ." So spoke the early Asiatic. Looking into the throats of today one wonders sometimes about the progress of tonsillectomy techniques over the past 3,000 years. Five hundred years later than these Indians, Hippocrates, speaking of inflamed tonsils, wrote, ". . . introduce the finger and push aside the tonsils, rub the uvula with dry flowers of copper, give warm gargles and externally apply warm plaster of barley-flowers cooked in wine and oil."

These recommendations of Hippocrates of the treatment of tonsillitis recall something very similar to the teaching on this subject not many years ago, when hot honey gargles were used inside the throat and flavored poultices outside. So 500 years after the Asiatics began removing tonsils by early 20th century techniques, treatment of the inflamed tonsil had become conservative, or medical, under the influence of Hippocrates.

Turning to the more serious angles of the subject, I am somewhat bewildered, after all these centuries of tonsillectomies, that there still is "a tonsil and adenoid ques-

tion." Perhaps, however, one should attempt to unravel the weird record of benefits from tonsillectomy and see if there are good factual and statistical data to support the removal of this organ. I will not waste time on a discussion of the benefits of tonsillectomy in such varied conditions as anorexia, mental deficiency, nosebleeds, pyelitis, the respiratory allergies, and cyclic vomiting. Kaiser³ in his classic monograph on "Children's Tonsils In and Out" comes closest to good statistical devices. His analysis of the facts are shrewd, and he makes few dogmatic claims for the real benefits of tonsillectomy. In fact, when Kaiser has finished comparing the persons whose tonsils had been removed with the controls who had not been subjected to tonsillectomy, he points out only four positive benefits from the removal of tonsils and adenoids over a 10 year period: 1. Throat infections were reduced in incidence. 2. The incidence of cervical adenitis was decidedly reduced. 3. There were 30% fewer first attacks of rheumatic manifestations in persons whose tonsils had been removed. Recurrent attacks were not at all affected by tonsillectomy. 4. The incidences of scarlet fever and diphtheria were lower in persons subjected to tonsillectomy. All other claims he looked upon as dubious and without good evidence to support them. The advent of chemotherapy appears only to have modified rather than altered Kaiser's claims.

Out of the morass of speculation concerning the tonsil and adenoid question there are a few specific matters to be considered from the viewpoint of the internist. First, what are the indications for removal of the tonsils and adenoids? An observation that clearly goes to the core of the question, and the one that has most influenced my own thinking on the subject, was made by Lyman Richards⁴ some years ago in his book, "Otolaryngology in General Practice." He said, "The best results of tonsillectomy are obtained where the symptoms have been clearly referable to the tonsils and associated lymphoid tissue." Conversely, he observes that the farther complaints are from the tonsils, the poorer the results are with their removal. This concept constitutes a philosophy concerning the indications for tonsillectomy, and over the years it has restrained those who regard it well from a multitude of tonsillar sins.

Second, the hazards of tonsillectomy should be no contraindication for surgery when the need is clearly present. Nevertheless the hazards are worth serious thought. Hemorrhages can usually be stopped; shock can be combatted with care; thymic disease can almost always be discovered before it causes difficulty; and lung abscess should become even rarer with the judicious use of antibiotics, provided too much reliance is not placed on their magical qualities. Still, to the internist, these accidents associated with tonsillectomy are cause for concern when the procedure is considered so trivial and when it is used as a treatment for reasons that are not always too clear. It is also only fair to admit that the reports from our medical centers of the hazards of tonsillectomy are of the best results that can be obtained in skilled hands and that the true incidence of deaths and complications in rural areas can never be determined accurately.

Regarding the hazards of tonsillectomy, it is interesting to note how meager and inadequate are the reports of death or its causes from this procedure. An effort has been

made to cull some data from the medical literature on this subject to supplement Kaiser's widely read report. Out of these explorations only three factual and original studies were turned up, from 1922 to 1952, with information on the hazards of tonsillectomy.

The first of these was a report by Hannau Loeb⁵ in 1922 on "Fatalities Following Operations Upon the Nose and Throat Not Dependent Upon Anaesthesia—a Study of 322 Hitherto Unreported Cases." On the basis of this study, Loeb commented:

The laryngologist has become an accomplished surgeon [this in 1922] with an enormous operative material. The work has become so attractive—or perhaps so remunerative, that there are 5,000 physicians according to the American Medical Directory, or one in every thirty practitioners in the country, who profess to be qualified to practice the specialty of Laryngology. These men have an important bearing on the well being of today.

TABLE 1.—Principal Causes of 332 Nonanesthetic Fatalities Following Nose and Throat Surgery

Cause of Death	No.	Percentage
Menigitis	125	40.0

Loeb sent out 5,000 questionnaires; 466 physicians reported no fatalities; 322 reported fatalities carefully collated; and 4,300 did not bother to answer. The results of his findings are seen in tables 1 and 2.

One must take these figures of Loeb's perhaps with a grain of salt since they are old. Nonetheless, this is one of the few available reports of a real effort to analyze the nonanesthetic causes of death associated with tonsillectomy and other upper respiratory surgery, not only in the highly skilled medical center but across the country as a whole. This cross section of the hazards of tonsillectomy interests the internist as much as the best results of our academic centers.

The second array of interesting data found concerned deaths associated with anesthesia. In 1946, Harold

5. Loeb, H. W.: Fatalities Following Operations upon the Nose and Throat Not Dependent on Anaesthesia, Ann. Otol., Rhin. & Laryng. 31: 273, 1922.

Bishop⁶ reviewed the anesthetic deaths occurring in the United States between 1922 and 1931, deriving most of his information from the United States Bureau of the Census. These figures are shown in table 3.

Over the years 1922 to 1931, 15% of all the anesthetic deaths were associated with removal of tonsils or adjacent lymphoid tissue. The incidence of anesthetic deaths with tonsillectomies should be no more than with other operations except that the total number will be greater with tonsillectomies because more such operations are done by whatever route the anesthesia is given. These figures of 1932 are also old, but no such statistics are available since then. The paucity of recent studies on the hazards of tonsillectomy is a sad commentary on the absence of intellectual curiosity in this important matter.

Third, data were unearthed from the "Registrar's Report of Massachusetts for the Year 1950" based upon the New International Classification of Statistical Data that revealed eight deaths associated with operations on the tonsils or adjacent lymphoid tissue. Four of the eight persons who died were children less than 10 years

infections except when breathing is interfered with by overgrowth of lymphatic tissue or when repeated bacterial infections localize in the tonsils or the tonsillar glands.

Andrewes,⁷ in his current studies of the common cold and other vital infections at the Harvard Hospital in Salisbury, England, is doing much to unravel the enigma of the natural history of these infections and the factors that influence them. "Sore throats" fall more and more into this group of viral infections, and tonsils and adenoids, present or absent, do not appear to play much part in their course or incidence. Furthermore, the general and less tangible factor of individual resistance and susceptibility to respiratory disease is all too generally disregarded. Andrewes, in human transmission studies with the virus of the common cold, has shown that immunity to it is short-lived, lasting rarely more than three months and often as little as one month. His uninfected controls did not have colds, nor even allergic rhinitis. Of the subjects in whom the cold virus was injected intranasally, 40% had colds and 10% had characteristic symptoms of a cold that spontaneously aborted within 24 hours. In 50% of those in whom the virus was injected no cold developed at all. This knowledge of the natural history of the common cold should be useful in evaluating upper respiratory disease and leave us skeptical of current "cures" or the effects of tonsillectomy on its incidence and prevention.

There are numerous systemic diseases in which the value of tonsillectomy is still under dispute because of conflicting experimental evidence or because of varying interpretation of personal experiences. Poliomyelitis is an outstanding example. There are differences of opinion concerning the influence of tonsillectomy upon the appearance of the serious bulbar forms of that disease.⁸ The portal of entry of the poliomyelitis virus or its route of transmission through the body is not definitely known. However, it is known that fatigue and trauma are conducive to the development of paralytic forms of the disease in epidemics when the virus is prevalent in the respiratory tract and feces of large sections of the community. To the internist it is logical that not only the removal of the tonsils and adenoids but any elective surgery of the respiratory or alimentary tract should be avoided when poliomyelitis is prevalent. Fear of cutting portals wide open for entry of the virus by blood, lymph channels, or nerve axones should stay the surgeon's hand.

Cunning's⁹ poliomyelitis-tonsillectomy survey in 1949 is of interest, if only for the defects of its statistical analysis. While Cuning sees no statistical evidence that tonsillectomies have any significant relationship to the increased incidence of bulbar paralysis, his figures are unconvincing. Eley and Flake^{8a} present a more critical review of this subject with evidence difficult to disregard concerning surgery of the lymphoid tissue of the nose and throat and the associated development of the more serious forms of poliomyelitis.

The internist believes that poliomyelitis is only one of the neurotropic diseases in which the trauma of tonsillectomy and adenoidectomy should be avoided in epidemics.¹⁰ Encephalitis of any type, influenza of proved type, with its more obscurely associated encephalitides, as well as epidemics of meningococcus meningitis should be signals for the avoidance of any unnecessary surgery

TABLE 3.—Number of Operating Room Deaths Associated with Anesthesia in the United States*

1931.....	678	86	12.7

* These data were derived from mortality statistics of the United States Bureau of the Census.

old, two more were between 11 and 20, one was 29, and one was 50 years of age. Most of these operations, therefore, would seem to have been routine procedures. All of the fatalities were nonanesthetic deaths. They all occurred in the small state of Massachusetts in the one year of 1950, but they give some indication of the mortality hazards of this operation if multiplied by the 48 states. The internist thus remains reserved in his attitude toward the removal of tonsils and adenoids, since a dead patient is not a good result.

Diseases of the respiratory tract, especially the common cold, are the subject of more pseudoscience and old wives' tales of "cures" than almost any other human affliction including the removal of the tonsils and adenoids. The internist looks with great skepticism upon the benefits of tonsillectomy in the prevention of respiratory

on the respiratory or alimentary tracts. There are no figures available and no experimental evidence to prove this wider concept. It is reasonable, however, that in epidemics the prevalence of serious neurotropic diseases of the central nervous system, obscure as to the portal of entry, should suggest the avoidance of any surgical trauma, especially the removal of tonsils and adenoids. Such a procedure lays bare a large surface of nasopharyngeal tissue where these viruses and organisms are found.

Rheumatic fever poses another question in regard to the removal of tonsils and adenoids. Before the days of chemotherapy, Kaiser⁸ stressed the importance of removing the troublesome tonsils of children and thereby reducing the subsequent incidence of the primary rheumatic infection by about 30%. Once the rheumatic state was established, the presence or absence of tonsils had little effect on the recurrence of rheumatic fever. Much informed opinion in northeast United States holds that chemotherapy is better when tonsils are present.

There are only two observations to make concerning diphtheria: First, diphtheria carriers should have their tonsils and adenoids removed as cleanly as possible, since chemotherapy without surgery gives unsatisfactory results in eradicating the carrier state as pointed out by Banks.¹¹ Second, the differential diagnosis of the diphtheritic throat and peritonsillar abscess may be externally difficult, as all of us are well aware.¹² In World War II, it was my experience that late palatal and peripheral paralyses and polyneuritis occurred with great frequency when the diphtheritic throat was lanced in error in the belief that there was an acute peritonsillar abscess.

The human body appears to abhor the removal of tonsils and lymphoid tissue of the nasopharynx, at least "before the tonsils have stopped growing." This fact is evidenced by the amount of lymphoid tissue that grows back after the larger tonsils and adenoids have been supposedly cleaned out surgically. Lingual tonsils, adenoids,

pharyngeal lymphatics, and lymphoid tissue in the fossae of excised tonsils all appear to make a stubborn and concerted effort to replace the excised organs. In fact, so frequent is the regrowth of the lymphatics that we are seeing today the widespread use of cathode rays to destroy these lymphoid tissues for life. Schultz and Robbins¹³ and Boies¹⁴ have pointed out that the delayed destructiveness of x-rays in burning the deep and superficial tissues of the head and face can be almost too extensive for belief.

As an internist I believe that too many tonsils are still being taken out, but I am open to persuasion that this is not true. I am not convinced, however, by the analyses of results based upon the individual case history of success or failure. Rather I am interested in the adoption of modern, life table methods of statistical analysis in a retrospective study for determining the benefits, the hazards, and the causes of death associated with the removal of tonsils and adenoids. Herein lies the kernel of the "question" of tonsillectomy.

Both the physician and the patient remain deeply indebted to the skilled otolaryngologist for the safe removal of tonsils and adenoids when the need exists. Nevertheless the physician should not regard the removal of these organs as a trivial procedure. Rather it is one requiring great skill in anesthesia, in operative technique, and in postoperative care in addition to careful selection based on the needs of the patient rather than the accessibility of the organ itself. It is indeed clear that the internist and the family doctor cannot escape their share of responsibility with the otolaryngologist in decisions regarding the need and the wisdom of removal of the tonsils and adenoids.

THE TONSIL AND ADENOID QUESTION AS SEEN BY THE PEDIATRICIAN

R. Cannon Eley, M.D., Boston

For some years it has been generally accepted that the tonsils and adenoids serve as a first line of defense in protecting the respiratory and alimentary tracts from bacterial invasion, and, as a result of this conception, some pediatricians, as well as internists, have gone so far as to believe that these tissues should never be removed or removed only in later life. Others, however, hold the view that the removal of tonsils and/or adenoids early in life does not increase the frequency of respiratory infection, and they advocate excision when the presence of these lymphoid tissues offers a hazard to the general health of the patient. This appears to be the sensible and practical position, rather than either of the two possible extremes. In discussing this question, it should be recalled that adenoid tissue and the palatine tonsils are normally present at birth. These structures generally increase in size until about the age of 3 to 5 years, after which time there is a retrograde process with almost complete elimination of adenoid tissue and a reduction in the size

of the tonsils. This normal process may be altered, however, in the presence of abnormal conditions such as repeated or chronic infections that of themselves may result in marked tissue hypertrophy and resulting chronic infection. It is in such conditions as this that the physician must weigh the effects being produced on the general health of the patient and then decide on tonsillectomy and/or adenoidectomy, regardless of age.

CONSULTATION WITH OTOLARYNGOLOGIST

How does the pediatrician look at the tonsil and adenoid question? Does he consider it only from the local manifestations, from the general health factors concerned, or from aspects such as recurrent tonsillitis in a child with congenital heart disease? These are all perti-

From the Department of Pediatrics, Harvard Medical School, and the Department of Medicine, Children's Medical Center.

Read in a Symposium on the Tonsil and Adenoid Question before the American College of Surgeons in Joint Session with the New England Otolaryngological Society, Boston, March, 1953.

nent questions, and before any of them are considered, a plea should be made for closer association between the otolaryngologist and the referring physician. To me it has always seemed poor practice of medicine to refer a patient to an otolaryngologist without first contacting him and explaining why his opinion is desired or why tonsillectomy and/or adenoidectomy are necessary; one cannot compare this situation with the referral of a patient with an obviously fractured leg to an orthopedic surgeon. In the former instances the previous history of the patient and the possible underlying hazards are really known only to the pediatrician (the family physician to children), and without this information the otolaryngologist may be at a complete loss as to why the patient was referred. Not every patient referred to the surgeon needs to have a tonsillectomy or adenoidectomy. Thus, the relationship between the two physicians is on a consulting basis, and only after such an understanding has been established can the question be solved.

IMPAIRMENT OF HEARING

The physician is familiar with tonsils that are so large that they force the uvula into the background and even a grain of corn cannot pass the barrier, and too there is the adenoid tissue that produces a deep bass sound during sleep, rather than the normal quiet purr. What is indicated in these situations need not be discussed; yet these local conditions, especially those involving the adenoid structures, may, and do, cause serious complications in infants and children. And here I have in mind particularly impairment of hearing, which may vary in degree from minimum to maximum. To me there is no greater or more serious problem. How often the physician is faced with the question of whether the child is mentally retarded or actually handicapped by impairment in hearing, hence appearing retarded! This question is of ever increasing magnitude and importance, and it often is treated so lightly at the expense of the patient's present and future health and happiness. The need of office and hospital services for persons trained in the art of detecting early changes in hearing ability, in my opinion, is one of the most important questions faced today, and the art is being developed. Classifying an intelligent deaf child as a mentally retarded person is a mistake that occurs too frequently.

The theme of the relationship of mastoiditis, with or without sinus thrombosis and septicemia, to chronically infected adenoid tissue is seen less often since the introduction of antibiotics and chemotherapy. Such agents, however, have had little, if any, influence on mouth breathing, the development of the so-called adenoid facies, inability to sleep because of impaired breathing space, and numerous other disturbances readily attributable to such chronic infections. In these conditions the answer is apparent, i. e., the removal of the infected tissues and/or irradiation as necessary. The quibble over age seems to assume academic proportions and is not of practical consideration if one is a practitioner of medicine.

GENERAL HEALTH FACTORS

What are the general health factors concerned in this question? I realize that this term is a loose one; yet it does connote some meaning. As with any low grade infection,

wherever its location, the patient does not feel well. There is listlessness, anorexia, anemia of varying degrees, apathy, loss of interest in usual activities; perhaps loss of weight, and, in general, a feeling of ill health. These symptoms appear quite readily in the young child, who usually is very busy with his enthusiastic activities and his school work and who suddenly or gradually develops the opposite attitude. In trying to evaluate properly such a situation, one should remember that it is not the bacteriological report on nose and throat cultures that decides the question. It is the history and clinical course of the patient. In my opinion, there is still a place for the clinician in the practice of medicine.

Much has been said about the relationship between infected lymphoid tissue and such conditions as rheumatic fever, chorea, nephritis, and nephrosis, but no proof has ever been advanced to support this contention. I do, however, believe, that patients with congenital heart disease may suffer severe complications by the presence of these sources of infection, and I have reference to the development of subacute bacterial endocarditis. There also are those instances in which infections of these structures may produce disturbances such as encountered in recurrent otitis media, sinusitis, and selected patients with infectious asthma, peritonsillar abscess, etc.

DANGERS OF AN OPERATION

How the pediatrician views the dangers or hazards associated with removal of the tonsils and adenoids should be considered from the psychological effect on the patient, as well as the operative procedure. Since this surgical procedure is an elective one and can be planned well in advance, there is no excuse for the element of surprise, as the child can be properly prepared for the event and so enter into it without undue fear or apprehension. The emotional trauma of years ago has been removed as physicians have improved their knowledge of the psychological effect of hospitalization on the child. Accompanying these improvements in the care of the patient, there have been advances in operative methods involving both anesthesia and surgical techniques; for example, having the patient in the head-down position during the operation has greatly reduced the hazard of aspiration of blood or fragments of tissue into the airway or lungs, thus minimizing these complications. The pre-operative and postoperative use of antibiotics and chemotherapeutic agents has likewise reduced the danger of blood stream infection and a competent physical examination prior to the operation has assured the family and the surgeon that all precautions have been taken. Thus, it would appear that under normal circumstances the dangers and hazards of this operative procedure have been reduced to a minimum when directed and performed by competent physicians.

I used "under normal circumstances"; these words were carefully and deliberately chosen, for I believe that circumstances do exist when such an elective operation is definitely not without hazard. As far back as 1910 Sheppard called attention to the possible relationship between the development of poliomyelitis of the bulbar type after tonsillectomy and adenoidectomy. Aycock and Luther in 1929 reaffirmed these observations by a study carried out in Massachusetts and Ver-

mont, and in 1938 sufficient evidence relative to this relationship was produced that it justified the withholding of this elective operative procedure in those areas where acute poliomyelitis was prevalent. Since that time many authoritative reports, both experimental and clinical, have appeared in the literature; yet there still exists a sizeable group of physicians who would try to convince others that such a relationship does not exist. I can only

state that, in my opinion and in spite of the cunningly prepared reports, I am convinced that this hazard is a real one and not one of fantasy or chance. In conclusion one may say that most pediatricians view the tonsil and adenoid question with respect, but they also view the general health of their patients with a greater respect and in selected instances and under proper circumstances advocate the removal of these lymphoid threats.

THE TONSIL AND ADENOID QUESTION AS SEEN BY THE OTOLOGIST

Gordon D. Hoople, M.D., Syracuse, N. Y.

With the change in otolaryngological practice, due to the advent of the antibiotics, it is an appropriate time to take a new look at the tonsil and adenoid problem from the otologist's viewpoint. This is particularly true in the light of the new emphasis on conservation of hearing that has come to the foreground in the past 10 years. In the past, tonsil and adenoid operations were often done without too much study and consideration of the need for their removal. The operation frequently was done rapidly and sometimes carelessly. Operatively, time was often given prime importance. Each tonsil was removed with a single manipulation of a guillotine, and the adenoids extracted with not much more than two or three swipes with a LaForce adenotome or an adenoid curet. I have seen the operation done in less than a minute. An operator with a good team of anesthetists and nurses could and did care for 10 or 12 patients in one hour. All this was not ideal, but it was reasonable when the main objective was the removal of tonsils and adenoids for the relief or prevention of such disorders as otitic infections, sinusitis, and lymphatic gland infections. Today, there is still the problem of otitic infections, sinusitis, and lymphatic gland infections, but more often now than previously, a loss of hearing is the reason for the removal of tonsils and adenoids. While it is true that tonsils, because of enlargement or severe infection, are an etiological factor in hearing loss, they are offenders in hearing impairment not nearly so frequently as the adenoid. I, therefore, would like to emphasize in the remainder of my remarks the importance of the adenoid in this regard and confine myself to this aspect of the tonsil and adenoid problem.

LOSS OF HEARING

In the Northeast, at least, the winter season is the dread of most otologists. This is the time of the year when the office is often filled with children who have inflammation or infection of their ears. When it is the former, it is almost always accompanied by the collection of some sterile fluid in the ear, that is, otitis media with effusion. This condition frequently is more difficult to treat and eradicate than infection, and neglect can result in partial, but permanent, loss of hearing. Too often children with inflammation and fluid in their ears do not come to the otologist. They remain in the office of the pediatrician, with the accompanying hearing loss undiagnosed or excused with the assumption that the child's lack of response to queries or commands is due to inattention and not to impairment of hearing.

Furthermore, the end-result of antibiotic treatment for an ear infection may be a sterilization of the infectious process with a residual otitis media with effusion. This is particularly true, in my experience, with penicillin therapy. The end-result in such an instance is the same as if there were no infection in the first place but only inflammation. With the subsidence of pain, temperature, and discharge (if such were present), the pediatrician is apt to consider the patient cured, although this is far from the truth. Fortunately, some pediatricians are sharply aware of this problem, but there are too many who do not concern themselves with moderate or slight hearing losses. The otologist can do nothing but sound this note of warning.

Not infrequently, a child who has had many abscesses in the ears instead of repeated minimal inflammatory attacks, will be brought to an otologist. Among the several causes for both these conditions, two stand out: infected lymphoid tissue in the nasopharynx and allergy. An unrecognized and undiagnosed allergic condition is often the reason why a child is subject to inflammation or infection in his ears. When, in addition to allergy, there is infected lymphoid tissue in the nasopharynx, the otologist is confronted with the problem of which of the two etiological factors is the more important. Should the adenoid tissue be removed and the allergy be neglected, or should allergic management be used with the hope that the infection will quiet and will not again bother the child's ears? In most instances, it will probably be wise to attend to both these etiological factors. Certainly, it would be unwise to pass over infected lymphoid tissue, for it is the most frequent cause of repeated trouble with the middle ear. On occasion, removal of a focus of infection will quiet an allergic mucosa, and it will not bother again unless it is prodded by another excitant.

If, then, the otologist is confronted with a patient who has some of these ear problems, it is his duty to advise a very thorough removal of the infected lymphoid tissue present. If infected tonsils are present, their removal should be included, but the careful removal of the nasopharyngeal disease is the more important. It does not matter what age the patient may be. I have removed adenoids from a child only 3 months old and have seen

Professor of Otolaryngology, Syracuse University Medical School.
Read in the Symposium on the Tonsil and Adenoid Question before the Sectional Meeting of the American College of Surgeons in Joint Session with the New England Otolaryngological Society, Boston, March, 1953.

infected adenoids in persons who are in their sixties. The time factor is important. Removal should be undertaken as soon as the local condition in the nasopharynx warrants surgery. Waiting for summer is often unwarranted, for the public has become so poliomyelitis conscious that one cannot operate during the summer and early fall months. A cogent reason why operation should be instituted as soon as possible is that another episode may be just around the corner, and this episode may be the one that will really cripple the hearing in one or both ears. Each attack is potentially a serious one. Every attack probably lays the groundwork for some loss of hearing, but one never knows which attack may leave a striking aftermath.

ADENOIDECTOMY UNDER VISION

How does one perform a careful adenoidectomy? Certainly not with a few careless applications of an adenotome. A careful adenoidectomy should be completed, so far as possible, under vision. It is not possible to remove, under vision, the last remnants in the vault, but it is possible immediately thereafter to visualize the vault to ascertain if the last remnants have been removed.

It is immaterial how the main mass of adenoid tissue is removed. This can be accomplished with the use of an adenotome or a curet. The careful removal of the remaining islands is, in my opinion, very important. Here is where the use of visual control contributes much. A very important landmark that can be seen without difficulty, if the soft palate is elevated, is Passavant's ridge. This is the name given to the upper border of the superior constrictor muscle. It will be noted as a distinct pad of tissue above which one looks directly onto the nasopharyngeal fascia if the adenoids have been removed. Only occasionally does the lymphoid tissue of the adenoid extend downward over Passavant's ridge in its midportion. Very often, however, lymphoid tissue can be seen lying on the lateral aspects of this ridge. There is a continuous mass that arises in the region of the eustachian tube, passes over Passavant's ridge and continues to be present behind the posterior pillar on the lateral surface of the posterior wall of the pharynx. This is commonly called the lateral band. It frequently is infected along with the tissue in the vault of the nasopharynx and should be removed. Sometimes, when the band is very large, removal can be accomplished with the judicious use of a grasping tenaculum and tonsil snare; usually, it is best done with a biting forcep. I find the use of a triangular forceps with a basket attachment preferable to any other. The bitten pieces will not then be dropped in the pharynx with the subsequent risk of inhalation. When the tissue over the lateral aspect of Passavant's ridge is removed, care should be taken that muscle tissue is not removed as well. This care should be exercised in all of the manipulations in the region of the ridge. Care should also be taken in this part of the operation not to injure the mucous membrane on the posterior aspect of the posterior pillar. If this is kept in mind and carried out, one need never fear a stricture of the nasopharyngeal opening; if neglected, such scarring may ensue and its correction prove tedious.

Above Passavant's ridge, all visible lymphoid tissue should be removed. This cannot be done with an adenotome. I cannot do it with a curet. I find it necessary to

use the biting forceps. I continue to remove tissue until the nasopharyngeal fascia is clean. Once it is clean, it is easily recognized, and, in my opinion, an adenoidectomy has not been done unless a clean nasopharyngeal aponeurosis is the end-result. As one works superiorly toward the vault of the nasopharynx, the ability to see is lost, and the biting forceps must be used carefully and wisely in this location. Fortunately, unless one bites too far laterally where the top of the eustachian cushion may be injured, there are no structures to be avoided. It is surprising sometimes to see how much additional tissue can be removed from this location after careful use of the adenotome has been exercised. If judgment and skill are used, tissue posterior to the eustachian tube can be removed in this biting part of the operation. It should be mentioned that the eustachian cushion can be mistaken for lymphoid tissue, and this mistake should be avoided.

All of the operation needs proper vision. Various operators use different methods to accomplish this. It does not matter what method is used so long as vision is obtained. I prefer the Lothrop retractor, but I have used others when it has not been available. It should be noted that all soft palates are not alike, nor are all nasopharyngeal openings of like measure. Thus, some nasopharynges can be seen better than others; but the attempt should be made in all. It seems hardly necessary to add that all this condemns the swiping of the nasopharynx with a gauze-covered finger, a procedure still in common use. This manipulation is simple testimony to the laziness and carelessness of the operator who uses it.

If an adenoidectomy is performed before a child is three years old, it is more than likely that a secondary adenoidectomy will be necessary a few years later. Even an older child with excessive lymphoid tissue at the time of a primary operation may subsequently require a secondary adenoidectomy. If these conditions are present in children who have been operated by the examiner, it is reasonable and right to request the privilege of reoperation.

This naturally brings up the question of secondary adenoidectomies. These are more difficult than the original. If one practices the procedures outlined above, it is amazing how often one sees infected lymphoid tissue bound down by scar tissue. No curet and no adenotome will remove this. It must be cut away, and it can best be done, in my opinion, with a proper biting forceps. This must be continued till all lymphoid tissue is removed. A secondary adenoidectomy often takes longer to perform satisfactorily than the primary one.

One comforting thought to the operator who follows this technique is that he will have less postoperative bleeding from the nasopharynx. Most nasopharyngeal bleeding comes from incompletely removed lymphoid tissue. If one sees that the bleeding is stopped at the time of operation, on rare occasion will one have to stop a postoperative or secondary hemorrhage. This of course, does not include the tonsil area.

USE OF A RADIUM APPLICATOR

In any discussion of infected lymphoid tissue in the nasopharynx mention is usually made of the use of the radium applicator. It is mentioned here only to recommend the avoidance of its use. When its use became popu-

lar in the United States, I was overseas in military service. After I returned, I used a radium applicator for a period of about two years. Because I failed to obtain satisfactory results, I became convinced that its use for the elimination of infected lymphoid tissue in the nasopharynx is ineffective. Since I have paid more attention to a complete adenoidectomy, my surgical results (post-operative inspection of the nasopharynx), the decrease in the incidence of ear infections, and the improvement in hearing in these patients have been gratifying. I have seen numerous five-year follow-up audiograms of chil-

dren who have been treated with radium, and in the aggregate, the hearing at the conclusion of this period showed no improvement over the pretherapeutic hearing test. I have not used a radium applicator for more than five years. I realize that there are physicians who hold an opposite view. Despite the possible harmful effects in the after years with the increased dosage now advocated, they continue to advocate the use of radium. There is no purpose, however, to a controversy in the matter since a carefully performed adenoidectomy abolishes the need for the use of radium.

THE TONSIL AND ADENOID QUESTION AS SEEN BY THE LARYNGOLOGIST

Lawrence R. Boies, M.D., Minneapolis

I was prepared in my discussion to refer to the historical items that Dr. Badger has already mentioned, particularly the fact that there is evidence that tonsil surgery was done 1,000 years B. C.¹ As I read this account, it occurred to me that here we are, nearly 3,000 years later, discussing the tonsil as a problem. I wonder if there is any other subject in medicine with so long a history, about which there is controversy today. That it is still a problem is obvious if one examines current medical literature. In the "Quarterly Cumulative Index Medicus" one finds that in the 10 years, 1942 to 1951 inclusive, there have been listed an average of over 100 papers per year concerning the tonsils and adenoids.

That it was a problem before the days of modern surgical anesthesia and technique is not surprising. That it should be a problem today, except for the injection of the idea of the possible relationship of tonsil and adenoid surgery to the incidence of bulbar polio, is not so easily understood. It could be that the following two reasons suggest the responsibility for the controversial aspects of the tonsil and adenoid situation: 1. The indications for tonsil and adenoid surgery in the ordinary practice of medicine is determined through superficial observation. Compare it in a sense to the all-too-current practice today of the hasty prescription of antibiotics. 2. The regard for this surgery as a minor procedure seems to justify its attempted performance by many who have not acquired skill in working in this area. These also could be the reasons for the poor end-results from tonsil and adenoid surgery in terms of expected relief from the situation for which the surgery was advised, the inadequate removal, and the morbidity associated with the operation. With these possibilities in mind, I would like to consider the aspects of this matter that apparently contribute to controversy by asking these three questions: 1. What are the present-day indications for tonsil and adenoid surgery? 2. What constitutes an operation that is skillfully and thoroughly done? 3. What are the hazards to this surgery?

PRESENT-DAY INDICATIONS FOR SURGERY

Since I completed a residency at the Massachusetts Eye and Ear Infirmary 22 years ago, I have performed tonsil and adenoid surgery, or tonsil or adenoid surgery alone, on about 4,000 patients. A majority of these have

been in children. In relatively few instances has adenoidectomy alone been performed. Rarely has adenoidectomy been done on an adult. Practically all of the children on whom I have operated have been referred to me by pediatricians. I believe that the level of pediatric practice is on a high plane in the city in which I work. This judgment is based on my observation of the intellectual curiosity these pediatricians exhibit and the continued interest on the part of most of them in pediatric teaching and research. A majority of them would be classed as conservative; one or two might have radical ideas. Out of this experience, I am inclined to list the indications for tonsillectomy and adenoidectomy in three simple situations that are easily understood. I believe that the pediatricians with whom I work would agree with me. Two of these indications are well defined and probably are acceptable to most clinicians. These are repeated attacks of tonsillitis, and hypertrophy of the tonsil or adenoid to the extent of obstruction.

In children who have several attacks of tonsillitis, the tonsils tend to enlarge; yet it is not uncommon to find very large tonsils in spite of a negative history for tonsillitis. In adults who suffer recurrent attacks of tonsillitis, the tonsil may be of the small fibrous type, more or less continuously injected at the margins. When the palatine tonsil is hypertrophied to the extent of obstruction, it is usually very large. There is a nasal quality to the voice; mouth breathing is the rule; the child's appetite is poor; and usually there is a history of a tendency toward frequent upper respiratory tract infection, often in the form of tonsillitis. In some instances this same picture is the result mostly of adenoid hypertrophy alone and the tonsil is relatively small.

The third situation is not so clearly defined as the two indications just discussed. When there is continued evidence in a particular case that the tonsil harbors chronic infection as manifest by a purulent expression or excessive formation of caseous material, tonsillectomy should

Professor of Otolaryngology, University of Minnesota Medical School. Read in the Symposium on the Tonsil and Adenoid Question before the Sectional Meeting of the American College of Surgeons in Joint Session with the New England Otolaryngological Society, Boston, March, 1953.

1. Mollison, W. W.: The Work of Samuel Sharp and His Predecessors on the Functions and Surgery of the Tonsils, *Guy's Hosp. Rep.* 78: 93-103 (Jan.) 1928.

be considered. Then there is the concept of focal infection that has apparently undergone considerable clarification in recent years.² Extremes of thinking concerning this concept are not uncommon, but it is probably safe to say that a majority of the medical profession who treat diseases in which infection plays a role have a sane attitude toward this concept. This majority seem to reason that, when a disease in which infection may play a role exists and when evidence of persistent or recurrent infection is present in the tonsils, the surgical removal of this possible source of infection is logical if the infection cannot be promptly eradicated with modern drug therapy.

A SKILLFUL AND THOROUGH OPERATION

I stated earlier in this discussion that the regard for this surgery as a minor procedure seems to justify its attempted performance by many who have not acquired skill in working in this area. This performance on the part of the unskilled accounts for the fact that at least one in four tonsillectomies is not well done and one in two adenoidectomies is poorly performed. These errors in a more or less standardized technique are not so much the lack of knowledge of what should be done as a poor technique in doing it. It has been my observation that two circumstances contribute materially to these errors. One is that the operation is performed hurriedly, and the other is that there is a lack of clear illumination and visualization of the entire tonsillar fossa and of the nasopharynx.

A hurried technique often means inadequate hemostasis, and this in itself contributes to poor visualization. There seems to be a confidence on the part of some surgeons that bleeding vessels in a tonsillar fossa will contract, which confidence would be lacking with the same-sized vessel and degree of bleeding in an abdominal operation. Clear visualization of what is being done demands good hemostasis and good illumination. In many instances this illumination will only be obtained from a headlight or reflected light. The surgeon who depends on the overhead light of the operating room may find himself severely handicapped. This can contribute to a poorly performed operation.

The most hurried part of the operation has always been the adenoidectomy. I stated earlier that one-half of the adenoidectomies are poorly performed. The reason for this is that this surgery is done in an area that is difficult to expose. I was taught in my general internship to scoop out a central mass of adenoid, check the result with an examining index finger and let it go at that. When these maneuvers were completed, the patient was hurriedly turned over on his side or face with the head low, so that he could bleed into a basin and not aspirate blood into his trachea. Since then, I have learned that it takes time and patience to perform an adenoidectomy well—it often requires 15 to 20 minutes or more—and that the technique requires a systematic procedure of planned scoops with an adenotome or strokes with a curet, then sponge pressure for hemostasis, then exposure of the site for visualization, and often the removal of more adenoid

tissue. Good hemostasis may require the application of hemostats and sometimes even sutures. A good adenoidectomy may require the use of special biting forceps, such as those designed by Meltzer, to remove hypertrophied masses of lymphoid tissue from the lateral pharyngeal wall and adjacent to the eustachian orifices. I subscribe to all that Dr. Hoople has said about the details of technique in removing lymphoid tissue from the nasopharynx.

THE BEST TECHNIQUE

The object of the operation is, of course, to accomplish a complete removal of the tonsils and adenoids with a minimum amount of trauma and adequate (which means complete) hemostasis. Whatever method accomplishes this for a particular surgeon must be considered to be the best technique. There was an era in which the so-called Sluder technique was popular. The original technique, I believe, called for deep nitrous oxide anesthesia, a rapid guillotining of the tonsils, and an equally rapid scooping out of adenoid tissue. The elapsed time for the surgeon's actual operative maneuvers approximated a minute in the demonstrations that I have seen.

I prefer a guillotine with a medium dull blade for the removal of the soft tonsils of young children. It has the advantages of leaving a smooth fossa and produces the minimum amount of trauma; however, its use does not shorten the time of operation when good hemostasis is obtained after the removal of each tonsil. There also may be the matter of removing a prominent plica triangularis, which may have to be done with scissors or snare or both, with additional attention to hemostasis. Sometimes, too, a remnant of actual tonsil is left because the guillotine cuts across a prominent nodule or misses an adherent portion of the tonsil at the upper pole or at the base. These may be overlooked with the "super-speed" technique.³ It is certain that adenoidectomy cannot be adequately done in many instances when there is speed and no careful inspection after hemostasis.

HAZARDS OF OPERATION

I once knew a pediatrician who stood far to the left in his antipathy toward tonsil and adenoid surgery. When a mother asked about the possible need for this surgery in her own child, this pediatrician could effectively halt her inquiry by saying, "Mother, do you know how many children died in this country last year from tonsil operations?" I might further qualify this particular pediatrician's judgment by adding the information that he administered cold vaccine to most of his patients who were subject to upper respiratory tract infections.

There has been mortality from tonsil surgery. Dr. Badger has already emphasized that. Occasionally I hear of such a tragedy in my community or in the state. In some instances it is due to the anesthesia, in others to hemorrhage. I have often heard the nurse anesthetist remark that the most difficult anesthetic to give and manage well has been the one for tonsil and adenoid surgery.

The advent of intratracheal anesthesia and the technique that has developed for this have, I know, eased my concern over the anesthetic in that there have been eliminated any periods of embarrassed respiration and anoxia, and the control of secretion or any blood in the trachea is made very easy and certain.

2. Coleman, G. H.: Present Status of the Concept of Focal Infection, *J. A. M. A.* 151: 280-285 (Jan. 24) 1953.

3. Boies, L. R.: Tonsillectomy in the United States, *Ann. Otol. Rhin. & Laryng.* 57: 352-363 (June) 1948.

The two objections to this method of administering the anesthetic have been the possibility of trauma to the vocal cords and the fact that the presence of the tube produces an obstacle to work around. We have found that selection of a tube of the proper size—one that does not fit tightly into the glottic space, and one that is made of an inert material, plus its introduction without trauma—eliminates any laryngeal reaction. There are adapters for its connection that allow a positioning of the tube to one side or other of the mouth so that it is practically out of the way (fig. 1 and 2).

Fig. 1.—Popular form of intratracheal tube with adapter connections.

With these advantages, control of the anesthetic should never be a problem. The nurse anesthetist experiences little difficulty in learning the management of the anesthetic through a tube. Dr. Ralph Knight, president of the American Society of Anaesthesiologists, has often made the statement that a surgeon who cannot insert an intratracheal tube should not be doing tonsil surgery.

Hemorrhage from tonsillectomy or adenoidectomy occurring within the first day of operation is more often the result of inadequate hemostasis at the time of surgery than any unusual situation related to the patient, or the condition of his tonsils and adenoids. Often, inadequate hemostasis means carelessness, speed, or lack of skill and experience. Slight bleeding about a week following the surgery is not uncommon, in my experience, and in most instances needs no special treatment. It is said to be the result of the separation of the membrane which normally coats the fossae, or in the nasopharynx to localized infection, or the separation of sutures.

In recent years a new hazard has been publicized—the vulnerability to poliomyelitis. Much has been written about this, some of which is controversial. It is not within the purpose of this discussion to consider the pros and cons of this controversy. It has been my contention that tonsil and adenoid surgery should be avoided in the presence of an epidemic of any disease. In recent months a new angle to this relationship has been stated to the effect that anyone of any age is more vulnerable to poliomyelitis and particularly to bulbar form if his tonsils and adenoids are missing.⁴ This is said to be true even though the tonsils and adenoids had been removed several years previously.

The first two hazards can be overcome by obvious means. The third, if time proves it to be one, will pass when poliomyelitis is controlled. Until then the indications for tonsil and adenoid surgery will undoubtedly receive the more thoughtful consideration that is justified and the

clinician will weigh the advantages in the total health picture against what hazards are faced when the operation is skillfully done with the full advantages of modern anesthesia. I suspect that since there seem to have been some advantages to the surgical treatment of tonsils for approximately 3,000 years, these advantages will continue in properly selected cases until all of the problems of upper respiratory tract infection and their sequelae are eliminated.

SUMMARY AND CONCLUSIONS

Surgery of the tonsil, discussed for nearly 3,000 years, is still controversial, probably first because the indications for its surgical treatment are often based on superficial observation and secondly because there is a morbidity and even mortality associated with it, because it is attempted by many who have not acquired skill through training and experience in working in this area. Tonsillectomy and adenoidectomy is justified in cases of repeated attacks of tonsillitis or adenoid infection, hypertrophy to the extent of obstruction, and when there is evidence of persistent chronic tonsillar or adenoid infection. A clean tonsillar fossa with the minimum of trauma to the pillars and muscular bed and thorough hemostasis are the marks of a skillful, carefully performed tonsillectomy. A thoroughly performed adenoidectomy requires good exposure of the nasopharynx, time, hemostasis, and visualization of the end-result. The hazard of hemorrhage is minimal if care and thoroughness are used. The anesthetic risks of periods of anoxia, uncontrolled aspiration of secretions into the lung, and other anesthetic hazards are practically eliminated with the best modern intratracheal method. The hazard of increased susceptibility

Fig. 2.—Intratracheal tube connected with anesthesia source. Because this connection is mobile and can be placed in either angle of the mouth, there is little interference from the tube in the area in which the surgeon works.

to bulbar poliomyelitis and of the greater possibility of death if the disease is contracted “call for sober judgment with regard to the desirability of tonsil removal except for excellent clinical indications. The nonremoval of tonsils may be as hazardous to a person or more so than their removal, for the chance of contracting poliomyelitis in a clinically recognizable form is not great.”⁴

90 S. 9th St. (2).

THE PHYSICIAN'S STAKE IN THE ARMY RESERVE PROGRAM

Major Gen. George E. Armstrong (MC), U. S. Army

and

Col. James B. Mason (MC), Army of the United States, Washington, D. C.

The defense of the United States is ultimately the responsibility of its citizens. Today sound war plans that can be quickly and skilfully executed are musts for success in modern conflict. In a republic, however, the attitudes of the people determine the strength or the effectiveness of the national preparations. Physicians have a large stake in these efforts. To achieve reasonable degrees of medical preparedness the mutually interdependent interests and the roles of the Army Medical Service and the health professions must be fully utilized. It is, therefore, timely and the objective of this essay, within limitations of security, to acquaint the medical body politic with the Army Medical Service plans that specifically deal with the reserve program and to suggest how the organized profession and the individual physician can assist in this important business. There must be neither intellectual nor physical blocks to prevent the fullest support of the Army Medical Service Reserve.

Facts without sugar coating, such as those contained in the recent paper by Moseley,¹ are illuminating. He has given a practical review of the current military medical effort, discussed the theoretical considerations of the "one military medical service" concept, pointing out its fallacy, has outlined in some detail the military requirements for physicians, and has commented on their varied employments. The readers of this paper will feel easier about professional utilizations should there be an all-out mobilization in the future. Another positive comment bearing directly on the thesis of our paper was a statement in the July, 1953, message of the President of the American Medical Association² on responsibilities of the physician in military medical matters. He invited suggestions to permit the effective fulfilling of the obligation of the organized profession.

MISSION

The guide to military planning is the mission, and, in the Armed Forces Reserve Act of 1952,³ public law (PL) 476, the Congress stated the mission of the Reserve as follows:

Section 201a.—The Congress hereby declares that the reserve components of the Armed Forces are maintained for the purpose of providing trained units and qualified individuals to be available for active duty in the Armed Forces of the United States in time of War or National Emergency, or at such other time as the National Security may require, to meet requirements of the Armed Forces of the United States in excess of those of the Regular components thereof, during and after the period needed for the procurement and training of additional trained units and qualified individuals to achieve the planned mobilization.

Surgeon General (Major General Armstrong) and Special Assistant to the Surgeon General for Reserve Forces (Colonel Mason).

2. McCormick, E. J.: *The President's Page*, J. A. M. A. 152: 1239 (July 25) 1953.

3. Public Law 476, 82nd Congress, The Armed Forces Reserve Act of 1952, effective Jan. 1, 1953.

Detailed plans for the employment of the Reserve Forces of the Army (the National Guard of the United States and the Army Reserve) have stemmed from this statement of mission.

PERSONNEL

Public law 476 also contains sound organizational and administrative directives that provide for the orderly operation of the reserve system in peacetime, furnish guidance for the correction of most deficiencies of earlier programs, and enhance the mobilization potential of this civilian element. To be effective, this Medical Reserve Force program requires active men in substantial numbers that it currently does not have. On examination, the means for procuring officers and enlisted men consist of a combination of voluntary and legal devices. This latter was authorized in public law 51, 82nd Congress. "The Universal Military Service Act," and requires that all enlisted men and those physicians, dentists, veterinarians, and certain other specialist personnel, who, subsequent to June 19, 1951, were less than 26 years of age on entering service and who have served two years on active duty, are obligated for six years' reserve service. Enlisted persons with an obligation now total several hundred thousand, and, although there is but a handful of officers presently, their numbers will increase as time passes. The obligatory procurement feature is weak because the law contains no real means of enforcement. The failure of the vast majority of this group of young men to recognize their reserve obligation or to participate in an active capacity constitutes a threat to national security and an avoidance of personal responsibility that is frightening. Affirmative action by highest authority is long overdue, and forthright measures must be employed if the reserve, as presently constituted, is to be saved.

The largely voluntary officer corps has suffered severe losses in the past five years because of retirements for age and physical deficiency and resignations prompted by press of business. The procurement of medical and dental corps reserve officers by voluntary means for inactive duty service has further lost ground since 1950, because the "Doctor Draft" act has utilized nearly 100% of the earlier source of officer recruits. After return from service, most of these men refuse to have any part of a military program, save in an all-out emergency. Unfortunately serious additional losses have resulted from failure to accept the indefinite term commission provided in the Armed Forces Reserve Act by many morally obligated to serve. Perhaps these losses can be attributed to poor motivation, fear of recall, and selfishness or apathy. The Army is to blame for other defections because of unfortunate promotion programs, some bad personnel policies rigidly enforced, and unrealistic training. These and the unfortunate frequent fluctuations of the troop basis during 1950 and 1951, causing the inactivation of units, have caused additional defections. The

events just cited are products of the "cold war" and reflect the instability of earlier higher level policies. Correction is at hand, however, because the reserve of all arms and services has now been reduced to a "hard core" that generally has a high morale and is deadly serious about its job. In general, with the application of valid policies and with but little supplementation of personnel and encouragement, the units and persons now on hand could quickly provide the basis for an effective force.

The Department of the Army has, through the application of realistic regulations and programs during 1952-1953, corrected most of the personnel and organizational defects already mentioned. For example, promotion boards were convened in all parts of the country during the summer of 1953 to consider officers on active duty, as well as those not in active service, for reserve advancement under public law 476. The troop program has been made firmer to eliminate the morale-shattering fluctuations. Training, while still in need of recurrent reexamination for validity, is improving month by month.

TRAINING

The training programs since the end of World War II, particularly those for the professional specialists, have been a source of great discontent to those who participated; hence the correction of this inadequacy deserves a little extra comment. The Surgeon General's approach to the modification of professional training programs was fully supported by the studies of two Department of Defense committees that conducted surveys of medical reserve matters. The Middleton Task Force,⁴ a civilian body that met during late 1949 and early 1950, surveyed armed forces medical reserve programs and submitted recommendations that assisted the Army greatly in the redirection of its over-all activities. A second committee, consisting of civilian and military members,⁵ was convened at Department of Defense level in the spring of 1952 to assess the training programs of the medical reserves of the armed forces. The findings and recommendations of this committee resulted in Department of Defense Directive 1215.4 on Nov. 26, 1952, to the secretaries of the Army, Navy, and Air Force. The grouping of medical service reserve career areas into command and staff on the one hand and professional on the other was recognized and affirmed thus giving support to an earlier view taken by one of us (J. B. M.)⁶ postulating the development of reserve career patterns and their use as a basis for the preparation of reserve training programs. In conformity with this concept, the directive required the incorporation of appropriately designed courses for professional specialists to supplement the otherwise generally adequate reserve instruction in each medical service. The responsibilities of the Surgeons General and their opposite numbers, at lower echelons of command, for planning and supervision were greatly enhanced by this directive.

The spirit and letter of the directive have been compiled within the Army by the development of a course of instructions to be known as "Military Medicine, phase 1," which becomes operative this fall. The program was conceived in the Surgeon General's office, while the details of the schedule, the assembling of supportive text ma-

terial, together with the preparation of a guide to insure a maximum degree of local program planning was accomplished under the direction of the Commandant, Army Medical Service Graduate School. The Commanding General, Army Field Forces, approved the program early in August and directed distribution to medical reserve units and to medical branches of U. S. Army Reserve schools. These latter elements are vehicles for the instruction of reservists who are not members of units. The topics included in the master schedule are shown in the table. Phase 2 of the course in military medicine and material for other corps will be issued later. The phase 2 program will be designed to acquaint professional personnel in medical staff and command matters in major medical headquarters and in duties of consultants and chiefs of section or service in military hospitals. The professional programs, such as have been cited, should breathe life into a most important segment

of the program, reawaken interest in those who have become inactive, and attract officer recruits. It is to be remembered that, in a mobilization, medical corps officer requirements for staff, command, and logistics are in the order of one to four with needs for professional personnel.

TROOP UNITS

It is pertinent to consider the troop units that are the strong right arm of any military program. The medical reserve troop program has been developed, as a portion of the Army Medical Service Mobilization Plan, to mesh

4. The Middleton Committee consisted of W. S. Middleton, M.D., chairman; W. McK. Craig, M.D.; J. Randolph Lovelace, M.D.; C. Raymond Wells, D.D.S.; and James B. Mason, M.D.

5. Committee on Medical Reserve Training, Reserve Force Policy Board, Office, Secretary of Defense, was authorized in March, 1952. The membership consisted of chairmen, (first) Brig. Gen. A. H. Schwichtenberg, (MC), U.S.A.F.; (second) Brig. Gen. J. O. Gillespie (MC), U.S.A., and (third) Brig. Gen. A. R. Gorby (MC), U.S.A.; members, Col. J. B. Mason (MC), Army of the United States; Capt. M. H. Porterfield (MC), U.S.N.R.; Col. A. L. Streeter (MC), U.S.A.F.; F. B. Berry, M.D., New York; and G. O. Broun, M.D., St. Louis; and a recorder without vote.

6. Mason, J. B.: Career Patterns for the Medical Reservist, Mil. Surgeon 108: 369-372 (May) 1951.

smoothly and in appropriate priorities with the troop list of the active Army in the event of mobilization. In like fashion the reserve troop list and priorities would be followed by the units required after both active Army and Reserve Force units have been called up. This latter force is termed the Army of the United States (A. U. S.) phase and will be cited below in connection with one-time affiliated units.

The troop list contains in appropriate numbers the various headquarters units (hospital center, group, and battalion headquarters), hospitals (1,000-bed general, station, evacuation, field, mobile surgical, and convalescent centers), and other combat and service support units. Over 80% of the troop units have been organized, although in far too many instances units are woefully short of personnel due to lack of local support. In 1952, the Army Medical Service in conjunction with the National Guard Bureau inaugurated a pilot program to ascertain the feasibility of organizing close division support hospitals (evacuation and surgical hospitals, mobile army) in the National Guard of the United States. Preliminary reports indicate substantial interest by the National Guard. If expanded, the program would benefit the states, furnish additional strong units for the medical troop list, and provide added career features for medical officers in the National Guard. All physicians should be fully aware of the even greater need for their support of the organic medical units of National Guard and Army Reserve divisions.

General hospitals affiliated with medical schools or large civilian hospitals provided very substantial support for the Army hospital programs in World War I and II. Although invited to reestablish units in the reserve at the end of World War II, very few of these institutions would participate because of the large amount of administration and time required for training by staff members. In 1952, the Army developed a fresh approach to the problem, inviting the institutions to furnish only key professional staff for general hospitals to be employed in case of war, in the Army of the United States phase. Where appropriate the old world war number would be again assigned. This plan did not require the development of an organization, the conducting of training programs, or the appointment of reserve officers. Currently, a high percentage of former sponsors have accepted thus making substantial contributions to long-range medical plans.

COMMENT

The historic position of the United States citizen is, in the main, one of abhorrence to service in the armed forces in peacetime. The rise of this country to leadership in the world community and the aggressive spirit of our enemy, who probably possesses both fission and fusion nuclear weapons, have added additional and grave responsibilities for its citizens. The security of the United States and the free world requires that the time-honored stand in military matters be reexamined in the light of this new status. Since the very beginnings of the nation, the active Army has formulated plans, and their execution in time of war has been largely accomplished by the civilian elements. Never again can this country afford the luxury of completing major plans after a war has started,

because there is no friendly nation strong enough to serve as a shield while the United States mobilizes. The catastrophe of a lost war would surely eliminate the American way of life! It is prudent, therefore, for the medical body politic to take a hard, realistic look at its peacetime responsibilities in long-range security planning. This long-range planning, as related to Reserve Forces, indicates completed positive action in several areas.

First, the Congress has provided a strong legal framework on which to erect a reserve edifice, if the lamentable picture with respect to active participation by those with a reserve obligation is excluded. Second, the Department of Defense and the Department of the Army, as pertinent, have developed valid Reserve Force programs and have issued workable policies and regulations. Third, the Army Medical Service through positive leadership has put realism into its reserve program. In addition, the more effective operation of the medical service by the wise inclusion of lessons of World War II and the Korean War into policy, regulatory and operational features of war plans have been assured.

CONCLUSIONS

It seems eminently clear from what has been set forth, that the Medical Reserve program has been well conceived and that provisions for its conversion into an effective military agency could be assured, provided solid support is forthcoming from the medical profession.

There are three areas in which organized medicine and the physician can be of great assistance. First, it must be recognized that the current world unrest will probably last for a long time and that a strong Army Medical Reserve Force is a must for the foreseeable future; this will mean hard work and sacrifice by all physicians. Under the Armed Forces Reserve Act, physicians with previous military service have wide choice in determining the degree of activity in which they wish to participate.

Second, physicians, as citizens, have a responsibility for national defense as it relates to Medical Reserve Forces. Physicians should support the country's defense by explaining the security needs of the nation to their patients and others in day-to-day conversations. In addition, within their own professional circle, they must by word and deed assist in creating an atmosphere of confidence in medical defense matters among the younger physicians.

Third, there must be greater physical participation by physicians in every unit requiring Medical Corps officers. The time devoted to this security effort should be put at the top of the list of extracurricular activities by every physician 45 years of age or younger. The requirement for personnel in local medical units can be readily secured from unit commanders by the military affairs committees of the county medical societies. This committee with the backing of the total membership should assist unit commanders in the procurement not only of medical officers but of other officers, nurses, dentists, veterinarians, and Medical Service Corps and enlisted men. Medical branches of Army Reserve schools, as well as reserves of one or both sister services—Navy or Air Force—need this vital push to bring the unwilling and the apathetic to do their duty. The alternative to serving and a willing

support of the Reserve Forces program by the medical profession can only mean the eventual withering to ineffectiveness of this civilian component.

There will surely be some who disagree violently and who will write seething letters of protest. This is healthy and a right of free Americans, but it is well for these persons to remember that the hazard of losing cherished rights and advantages has never been greater since Revolutionary days. Resolute and collective support for the medical reserve program from the grass roots is a must and it must come now! The Army Medical Service has done and will continue to do its part. It's your Army! It's your country!

CLINICAL NOTES

MULTIPLE EPISODES OF CARDIAC ARREST

REPORT OF A CASE

Brooke Roberts, M.D.

Truman G. Schnabel Jr., M.D.

and

I. S. Ravdin, M.D., Philadelphia

Successful restoration of cardiac function on four separate occasions in a single patient over a 10 day period following long periods of circulatory cessation seemed sufficiently unusual to warrant reporting. Of additional interest is the fact that at least two of these episodes were associated with ventricular fibrillation, and all attempts to prevent their recurrence were unsuccessful.

REPORT OF A CASE

A 68-year-old housewife was admitted to the hospital of the University of Pennsylvania on Oct. 22, 1952, for closure of a transverse loop colostomy. In June, 1952, an operation performed elsewhere for diverticulitis had resulted in the formation of multiple pelvic abscesses. At the time of operation, it was necessary to remove approximately three-fourths of her small intestine and to perform a transverse loop colostomy. Subsequently diarrhea developed, with 5 to 10 stools a day, and her weight fell from 130 to 100 lb. (59 to 45.4 kg.). The transit time from mouth to colostomy was 30 minutes. A high caloric diet and blood transfusions were only slightly beneficial to her general condition, and it was felt that closure of the colostomy would decrease diarrhea and alleviate her problem considerably.

Her history revealed that at the age of 8 she had had chorea and as a child had many sore throats. In 1938 she had been treated with rest and digitalis because of "nerves." At the time of admission she stated she had some precordial pain on exertion and mild ankle edema after prolonged periods of standing.

Physical examination revealed her to be a cheerful but emaciated woman in no acute distress. Her blood pressure was 140/84 mm. Hg and her pulse 96; her temperature and respirations were normal. Her skin was loose and dry. An arcus senilis was present bilaterally, and fundoscopic examination showed arteriolar narrowing of the retinal vessels. Cardiac examination revealed the apex beat to be in the fifth interspace, 8 cm. from the midline. There was a soft apical systolic

murmur and a split mitral first sound. The rhythm was regular, with an occasional extra systole. There was no venous distention. The chest was clear. A colostomy was present in the right upper quadrant. Rectal examination revealed some firmness in the cul-de-sac.

Laboratory studies revealed a hemoglobin level of 55% and a leukocyte count of 5,500. Her serum protein level was 5.9 gm. per 100 cc., and urinalysis revealed no abnormalities except for the presence of 8 to 10 leukocytes and 1 to 3 casts per high power field (necatheterized specimen).

After transfusion of 1,500 cc. of whole blood, her hemoglobin level rose to 83%. Preoperatively a thin membrane that had re-formed between the limbs of the colostomy was broken down again. On Oct. 31, 1952, an intraperitoneal closure of her colostomy was accomplished under spinal anesthesia. The procedure was tolerated well, and she returned to her room in good condition.

Postoperatively she seemed to do satisfactorily but, because of nausea, suction drainage was continued for two days. On the day after operation chemical studies revealed a serum chloride level of 80 mEq. per liter and a carbon dioxide content of 32 mM. During the next 36 hours, she was given 3,500 cc. of saline solution intravenously and by Nov. 2, 1952 (her second postoperative day), she felt considerably stronger. On Nov. 3, 1952, she started passing gas from the rectum. Chemical studies on that day revealed a serum chloride level of 92 mEq., carbon dioxide 34.2 mM., sodium 144 mEq., and potassium 2.7 mEq.

First Cardiac Arrest.—On the morning of Nov. 4 her status seemed good and oral administration of fluids was started. Her temperature and respiration were normal, and her pulse was 84. While sitting in bed talking, she suddenly began to have a convulsion. The convulsion was generalized, and upon its cessation she was apneic and pulseless. When seen four minutes later by an intern, she appeared moribund. He struck a sharp blow on the precordium, with a resultant immediate resumption of respiration and return of her pulse. Administration of oxygen was started, and within several minutes her blood pressure was 100/50 mm. Hg and her pulse and respirations were regular, but she remained unconscious. Fifteen minutes later, her pulse became grossly irregular, her blood pressure fell to 50/30, and Cheyne-Stokes respiration developed. Then 45 mg. of ephedrine were given intravenously, and her blood pressure rose to 90/50. An electrocardiogram taken at this time (see figure) showed auricular fibrillation and ST segment depression in all chest leads. It was interpreted as being indicative of diffuse myocardial ischemia and anoxia. These changes, it was thought, might be due to myocardial infarction, pulmonary embolism, or merely severe anoxia.

Two hours following the convulsion, spontaneous motion was first noted in her extremities. Four hours following the seizure, her blood pressure had risen to 178/90 and then gradually returned to her normal level of 130/70, with a regular but rapid pulse. Twelve hours after the episode, she was talking but seemed confused. During this 12 hour period, she was given 1,000 cc. of 0.6% potassium chloride, with 0.425% sodium chloride and 1,500 cc. of 5% dextrose in water. Heparin was given because it was thought that she had had a coronary occlusion or pulmonary embolus.

On the following morning, Nov. 5, 1952, she showed further improvement and could answer most questions. Her pulse was regular at 80, and her blood pressure 140/60. She had no chest pains. An electrocardiogram showed less depression of the ST segments and was interpreted as showing evidence of recovery from diffuse myocardial anoxia. Oral feedings were again instituted. Her condition seemed good during the next few days, but her memory for recent events was somewhat clouded.

Second Cardiac Arrest.—On the morning of Nov. 9 (five days after her initial cardiac episode) the second attack occurred while she was drinking a glass of milk. She suddenly became rigid, and again her pulse was unobtainable and her respirations ceased. This time a blow on the chest by her nurse was ineffectual, so administration of artificial respiration and oxygen by inhalation was started immediately. Five minutes later an intern reached the bedside and struck the chest with his fist, and again her pulse and respiration were restored.

After resumption of cardiac activity, the patient was hypotensive. Arterenal intravenously was therefore utilized to maintain a relatively normal blood pressure. An electrocardiogram taken soon after this episode showed some ST segment depression and T-wave changes that were little different from the electrocardiogram taken four days previously. Auricular fibrillation was present. The possibility of the electrocardiographic changes being due to electrolyte imbalance was raised at this time.

After this attack she was unconscious for four hours. When consciousness was regained, the blood pressure was 100/60 and the pulse was again regular. On the following day, Nov. 10, 1952, she was mentally alert. Her pulse was regular, with an occasional extrasystole. There were no signs of cardiac failure. Oral feedings were instituted and were associated with five

Electrocardiographic tracings of woman who had multiple episodes of cardiac arrest. The upper nine leads were taken one hour after the initial attack. The generalized ST depression and the prolonged QT interval can be seen. The serum potassium level at this time was 2.5 mg. per 100 cc. The lower three leads were taken 24 hours after the fourth attack. The QT interval is still prolonged, but the ST depression has disappeared. The serum potassium level was 4.7 mg. per 100 cc. (The electrocardiogram was retouched for reproduction.)

loose stools during the day. Chemical studies showed a serum chloride level of 91 mEq., sodium level of 138 mEq., carbon dioxide content of 40.5 mM., and potassium level of 2.5 mEq. Because of the diarrhea and low serum potassium, she was given 1,000 cc. of 0.6% potassium chloride with 0.425% sodium chloride intravenously. Administration of heparin was continued.

Third Cardiac Arrest.—On the morning of Nov. 12 her third episode of cardiac dysfunction and respiratory arrest occurred. Despite several blows on the chest that resulted in one or two heart beats, she remained otherwise pulseless and apneic for approximately 10 minutes. Nasal administration of oxygen,

however, had been started immediately, and during the latter half of this period mouth-to-mouth respiration was employed. The chest was then opened through the fourth left interspace and cardiac massage started. The heart was found to be in ventricular fibrillation. While cardiac massage was carried out and oxygen administered by mask and bellows, she was taken to the operating room. There 1,000 cc. of blood were given intravenously under pressure, and after manual massage had been carried out for at least 25 minutes and following the second series of electric shocks with a defibrillator, an effective rhythm was restored. The chest was then closed. She responded surprisingly rapidly, and by early afternoon was awake and recognized other persons. Her blood pressure was then 120/70, and her cardiac rhythm regular. Chemical studies done immediately after this last episode showed her serum chloride level to be 90 mEq., carbon dioxide 30 mM., sodium level 141 mEq., potassium level 2.4 mEq., and calcium level 7.8 mg. A dose of 500 mg. of procaine amide (Pronestyl) hydrochloride every fourth hour was given intramuscularly but was discontinued at midnight because of a falling blood pressure. During the evening, her blood pressure dropped to 80/55 and remained low for the remainder of the night. During the night she received a liter of 0.6% potassium solution and 10 cc. of 10% calcium gluconate intravenously. This was repeated the following morning.

Fourth Cardiac Arrest.—On Nov. 13, despite hypotension, 400 mg. of procaine amide every fourth hour was again given intramuscularly because of the development of premature beats of ventricular origin. In addition, 4 cc. of arterenal were given in an intravenous drip rapidly enough to maintain her systolic pressure at 100 mm. Hg. Four hours after the last dose of procaine amide and two hours after administration of arterenal was started, her fourth episode of cardiac arrest occurred. Her chest was opened three minutes following the onset of the attack, and her heart was again found to be in ventricular fibrillation. One minute after institution of cardiac massage and without the use of drugs or electrical defibrillation, her heart began to beat effectively. While cardiac massage was being carried out, she actually regained consciousness. She was again taken to the operating room, and her chest then was closed after induction of anesthesia with cyclopropane and ether. During the operative procedure 500 mg. of procaine amide were given intravenously to control the numerous ventricular extrasystoles. One hour later another 400 mg. of procaine amide were given intravenously. Because of persistent hypotension, arterenal was again used intravenously and at the same time, because of runs of ventricular extrasystoles, 400 mg. of procaine amide were also given intravenously. Subsequently she was given 0.6 gm. of quinidine, which resulted in marked widening of the QRS complexes but no decrease in the number of ventricular extrasystoles. Two and one-half hours after the use of arterenal and shortly after the use of quinidine, the patient became pulseless. Spontaneous respiration, however, continued, and she remained conscious. The electrocardiograms showed ventricular tachycardia to be present. In an effort to revert this arrhythmia to a normal cardiac rhythm she was given in succession intravenously, 1/150 grains (0.4 mg.) of atropine sulfate, 0.5 gm. of magnesium sulfate, and another 100 mg. of procaine amide, but the tachycardia persisted. One-half hour after the onset of tachycardia, 500 cc. of a 1.2% solution of potassium chloride were infused rapidly. One-half an hour later, the rhythm changed back to one in which the AV node appeared to be the pacemaker, and her blood pressure then gradually rose during the night to a level of about 80/60.

During the 24 hour period ending at 7 a. m. on Nov. 14, 1952, she received a total of 5,950 cc. of fluids intravenously, 2,000 cc. of which were in the form of whole blood. Her urinary output for this period was 110 cc. Although slightly incoherent, she was fully conscious. Chemical studies revealed the following values: 94 mEq. of chloride, 142 mEq. of sodium, 4.7 mEq. of potassium, 8.8 mg. of calcium, 28.8 mM. of carbon dioxide, and 28 mg. of urea nitrogen per 100 cc. Gradually during the day, her blood pressure fell to 60/40, and she became more confused and agitated. On the morning of Nov. 15, her urinary output for the previous 24

hour period had been 60 cc. Because of the hypotension and consequent oliguria, ephedrine was again given by drip in spite of its hazards in an attempt to raise her blood pressure. Two hours after the institution of this therapy, her blood pressure rose to 120/70, her pulse rate was 80, and respiration 16. During the next 24 hours, her blood pressure was maintained at 120/80. Every four hours 400 mg. of procaine amide were given to reduce the irritability of her heart. Oral feedings were again instituted. During this 24 hour period her urinary output rose to 195 cc.

On the morning of Nov. 16, her blood pressure was 120/80 and her general condition seemed fair. Her blood urea nitrogen level was 47. The dose of procaine amide was decreased to 250 mg. every sixth hour. At this time it was first noticed that her vision was poor. Attempts to visualize her eyegrounds were unsuccessful. Numerous rales were noticed in her chest.

By the morning of Nov. 17 we were more encouraged, as she had passed 500 cc. of urine during the previous 24 hour period, and her blood pressure remained at 120/80, her pulse in the 90's and her respirations around 26. At 9:35 a. m. on that day, however, she had another sudden episode and died without further resuscitative measures being attempted.

Autopsy Report.—An autopsy was performed with the following significant findings: In the thorax there was a "moderate amount" of straw-colored fluid in the right pleural cavity. The left pleural cavity contained cloudy serosanguinous fluid and many fine fibrinous adhesions. The left lung was stuck to the pericardium by recent adhesions associated with some purulent material.

The pericardium was inflamed, but the pericardial cavity was clear and there were no adhesions within it. The heart weighed 400 gm. and externally appeared normal except for an ecchymosis involving the right atrium. The right atrium and ventricle were dilated but the other chambers were normal. The valves were smooth and intact. The myocardium was paler than usual, but there was no area of softening or scarring.

The lungs, especially the left, were both partially atelectatic. There was very little gross edema fluid. There were a few small hemorrhagic consolidated areas, which were believed to be recent infarcts, but no emboli or thrombi were found in the larger vessels. A few thrombi were found in small pulmonary vessels. Microscopically much vascular congestion and some edema was present. The left lung showed active pleural reaction but no true bronchopneumonia.

Except for moderate atherosclerosis, the great vessels were normal. The liver showed passive congestion, and the spleen showed a recent hemorrhage. The intestinal tract was remarkable primarily for the fact that only 5 ft. (152 cm.) of small intestine remained between the ligament of Treitz and the cecum. There was a small fistulous tract from the site of closure of the colostomy through the abdominal wound.

The appearance of the kidneys was normal. On cut section, they showed good corticomedullary differentiation. Microscopically the vessels were congested, especially in the medulla. There were mild arteriosclerotic changes with thickening of the arteries, occasional hyalinized glomeruli, and some lymphocytic infiltration. The adrenals were of normal size, but the cortical tissue showed depletion of lipoid substance. The brain showed edema of the leptomeninges and a soft hemorrhagic area on the right parietal cortex about the size of a quarter of a dollar. There was no blood in the ventricles.

COMMENT

When the circulation has been arrested by asystole or ventricular fibrillation and death is imminent, thoracotomy and cardiac massage have generally been advocated as the form of resuscitative therapy to be used.¹ The case history presented above clearly shows that this form of treatment not only is lifesaving but may be carried out successfully twice in the same person. Although recently it has received relatively little attention in the literature, it has been known that under such circumstances a strong blow struck on the precordium may restore an effective circulation to a person with

so-called cardiac arrest.² In this patient the need for thoracotomy was obviated on two occasions by a simple blow on the chest. The speed and ease with which the precordium may be struck certainly justifies the trial of this procedure in many cases of cardiac arrest before cardiac massage is undertaken. Such treatment can be tried while a knife is being obtained.

It is impossible to state with certainty the type of cardiac dysfunction that was present during the episodes that were terminated by striking of the patient's chest. It seems most likely that the underlying mechanism was that of prolonged asystole, since spontaneous recovery from ventricular fibrillation, although reported,³ is rare. Ordinarily electrical defibrillation or the use of drugs is required before a normal rhythm can be regained. Two phenomena, however, that were observed during those episodes in which the heart was actually seen to be in ventricular fibrillation might indicate that such an arrhythmia was present during the first two attacks that were terminated by a blow on the chest, namely, (1) during the third attack repeated blows were followed by momentary effective cardiac beats and (2) during the fourth attack an effective beat was restored to the heart by massage alone without the use of drugs or electrical defibrillation.

The usually listed causes of ventricular fibrillation and cardiac standstill, or at least factors contributing to their development, are oxygen lack, toxic agents,⁴ either anesthetic or medicinal, reflex stimuli, trauma,⁵ electrical shock,⁶ and electrolyte imbalance.⁷ In this patient the only one of the above factors that might have played a role in the development of the first three attacks is an electrolyte imbalance. The fourth and fifth, or terminal episode, might also be related to the use of arterenol and ephedrine.

One can only speculate on the relationship of the electrolyte disturbance to the myocardial irritability present in this patient. Owing to prolonged diarrhea and inadequate absorption from her shortened bowel, she was depleted of many substances. The serum potassium level was low until two days prior to death and in retrospect should have been corrected with more vigor. The development of ectopic rhythm in the presence of low serum potassium has been reported,⁸ and Bellet⁹ has caused a ventricular tachycardia in a patient with low serum potassium to revert to normal rhythm by giving potassium chloride intravenously. Ventricular fibrillation

9. Bellet, S.: Personal communication to the authors.

has been reported in the presence of hyperpotassemia,⁷ but no such arrhythmia has been noted as a result of hypopotassemia. Although numerous patients have had lower serum potassium levels and more marked electrocardiographic changes than this patient without arrhythmia, it is entirely possible that the intracellular potassium deficit was of a greater magnitude than the serum levels indicated and was therefore related to the development of the episodic attacks reported above.

During this patient's illness, serum calcium levels also were moderately depressed. These, too, may have played some part in the electrocardiographic changes seen, but it seems unlikely that this degree of calcium deficiency was the sole causative factor in the production of her attacks of cardiac dysfunction. In one determination, the serum magnesium level was found to be normal. Whether some other unstudied ion was a factor in the development of these circulatory episodes cannot be said.

It is seldom that patients in whom cardiac arrest occurs on the hospital wards survive, as precious time is usually lost before circulation can be restored. It is of interest that this patient had three separate episodes of arrest of longer than four minutes' duration (the usually accepted upper limits for effective restoration) with full return of consciousness, and significant permanent damage to the nervous system did not appear to have occurred after the first two occasions.

SUMMARY

A case is reported with recovery on four separate occasions from prolonged episodes of cessation of circulation due in at least two instances to ventricular fibrillation. Efforts to prevent recurrence, however, were unsuccessful. It is suggested that in many instances of so-called cardiac arrest the precordium should be struck forcefully several times prior to use of thoracotomy and cardiac massage to restore the circulation. The possible relations of the development of this patient's episodes of cardiac arrhythmia to an electrolyte imbalance are discussed. It is felt the episodes of cardiac arrest may well have been related to depletion of intracellular potassium.

Lupus Erythematosus may present as a skin disease, as a subacute generalised disease or as an acute fulminating illness. Variations between these types are common and the manifestations of any of the generalized forms are protean. It is possible that the cutaneous form is, in fact, part of a generalized disease, since nearly all cases show a raised sedimentation rate, some show the presence of lupus erythematosus (L. E.) cells in defibrinated blood, and many patients remark on the feeling of increased well-being when the cutaneous lesions are controlled by treatment. . . . A case of subacute disseminated lupus may simulate many other conditions. It may present, for instance, as rheumatoid arthritis, atypical rheumatic fever with renal involvement, nephritis, pyrexia of unknown origin, pleural or pericardial effusions, lymphadenopathy, splenomegaly, rashes not necessarily of the common type, and in many other ways. Diagnosis may be helpful by finding anaemia, leucopenia, a high sedimentation rate, a reversed albumin/globulin ratio of the plasma proteins and red cells in the urine. The diagnosis is clinched by finding L. E. cells in suitable preparations of the blood.—F. Page, M.D., Mepacrine and Lupus Erythematosus. *Archives of Midlex Hospital*, October, 1953.

COUNCIL ON FOODS AND NUTRITION

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council.

JAMES R. WILSON, M.D., *Secretary.*

Gerber Products Company, Fremont, Mich.

Gerber's Strained Orange Juice.

This product is prepared from Florida oranges. It is processed and stored according to standards adopted by Gerber Products Company. These have been examined and accepted by the Council. The following information was submitted by the company. The juice is finely strained; the peel oil content is maintained at a point below 0.010%; dextrose in small amounts is added, when needed, for the maintenance of a sugar-acid ratio within specified limits; and the product is vacuum packed in 4½ ounce metal containers. The average ascorbic acid (vitamin C) content for the 1953 pack was 54.3 mg. per 100 ml. at the time of packing. The average caloric value is 14 calories per ounce.

"Junket" Brand Foods, Division of Chr. Hansen's Laboratory, Inc., Little Falls, N. Y.

Orange Flavored "Junket" Baby Rennet Mix.

Ingredients: Granulated sugar, confectionery sugar 6x, gum arabic, calcium phosphates, concentrated orange oil, U. S. certified color, and powdered rennet extract.

Analysis (submitted by manufacturer).—Total solids 99.7%, moisture 0.30%, ash 0.56%, fat none, protein trace, carbohydrate 97.2%, and undetermined organic matter 1.94%.

Calories.—3.89 per gram; 110.5 per ounce.

Use.—As a milk dessert in infant feeding.

Raspberry "Junket" Baby Rennet Mix.

Ingredients: Granulated sugar, confectionery sugar 6x, arrow-root starch, raspberry extract solids, calcium phosphates, powdered rennet extract, and U. S. certified color.

Analysis (submitted by manufacturer).—Total solids 99.5%, moisture 0.5%, ash 0.5%, fat none, protein trace, carbohydrate 98.5%, and undetermined organic matter 0.5%.

Calories.—3.94 per gram; 111.9 per ounce.

Use.—As a milk dessert in infant feeding.

Vanilla "Junket" Baby Rennet Mix.

Ingredients: Granulated sugar, confectionery sugar 6x, calcium phosphates, true vanilla solids, gum tragacanth, powdered rennet extract, artificial vanilla, and U. S. certified color.

Analysis (submitted by manufacturer).—Total solids 99.8%, moisture 0.2%, ash 0.7%, fat none, protein trace, carbohydrate 97.7%, and undetermined organic matter 0.4%.

Calories.—3.94 per gram; 111.9 per ounce.

Use.—As a milk dessert in infant feeding.

George B. Vrooman, Inc., Philadelphia.

Tux Brand Dietetic Pack Cut Green Beans

This product consists of Tendergreen variety beans, packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 5.2%, moisture 94.8%, fat extract 0.11%, protein (N × 6.25) 0.88%, crude fiber 0.53%, available carbohydrate 2.92%, and sodium 1.02 mg./100 gm.

Calories.—0.17 per gram; 4.8 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Tux Brand Dietetic Pack Cut Wax Beans

This product consists of Kinghorn variety wax beans, packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 4.6%, moisture 95.4%, fat extract 0.09%, protein ($N \times 6.25$) 0.82%, crude fiber 0.54%, available carbohydrate 2.37%, and sodium 0.80 mg./100 gm.

Calories.—0.13 per gram; 3.7 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Tux Brand Dietetic Pack Sliced Beets

This product consists of Detroit dark red beets, packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 0.05%, moisture 92%, fat extract 0.05%, protein ($N \times 6.25$) 0.90%, crude fiber 0.53%, available carbohydrate 5.53%, and sodium 46.50 mg./100 gm.

Calories.—0.26 per gram; 7.4 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Tux Brand Dietetic Pack Diced Carrots

This product consists of Red Cored Chantenay carrots, packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 6.56%, moisture 93.44%, fat extract 0.06%, protein ($N \times 6.25$) 0.78%, crude fiber 0.60%, available carbohydrate 4.04%, and sodium 50.1 mg./100 gm.

Calories.—0.20 per gram; 5.7 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Tux Brand Dietetic Pack Cream Style Corn

This product consists of Golden Cross variety corn, packed in water without any added sugar or salt.

Analysis (submitted by distributor).—Total solids 22.7%, moisture 77.3%, fat extract 1.06%, protein ($N \times 6.25$) 2.56%, crude fiber 0.32%, available carbohydrate 17.88%, and sodium 3.20 mg./100 gm.

Calories.—0.91 per gram; 26 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Tux Brand Dietetic Pack Whole Kernel Corn

This product consists of Tendermost variety corn, packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 17.4%, moisture 82.6%, fat extract 0.51%, protein ($N \times 6.25$) 2.04%, crude fiber 0.33%, available carbohydrate 13.81%, and sodium 1.2 mg./100 gm.

Calories.—0.68 per gram; 19.3 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Tux Brand Dietetic Pack Sweet Peas

This product consists of peas (Surprise variety), packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 11.7%, moisture 88.3%, fat extract 0.20%, protein ($N \times 6.25$) 3.14%, crude fiber 1.34%, available carbohydrate 5.33%, and sodium 8.58 mg./100 gm.

Calories.—0.36 per gram; 10.2 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Tux Brand Dietetic Pack Spinach

This product consists of Northland-Viking spinach, packed in water without any added salt.

Analysis (submitted by manufacturer).—Total solids 5.7%, moisture 94.3%, fat extract 0.31%, protein ($N \times 6.25$) 1.83%, crude fiber 0.60%, available carbohydrate 1.22%, and sodium 9.10 mg./100 gm.

Calories.—0.15 per gram; 4.3 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Mead Johnson & Company, Evansville, Ind.

Sustagen

Ingredients: Milk solids not fat, whole milk powder, Dextri-Maltose, calcium caseinate, dextrose, iron sulfate, vitamin A palmitate, calciferol, thiamine hydrochloride, riboflavin, niacin,

amide, calcium pantothenate, pyridoxine hydrochloride, choline bitartrate, folic acid, vitamin B₁₂ (crystalline), and ascorbic acid.

Analysis (submitted by manufacturer).—Total solids 97.5%, moisture 2.5%, ash (minerals) 4% (including calcium 0.7%, phosphorus 0.5%, and iron 0.003%), fat 3.5%, protein ($N \times 6.35$) 23.5%, and carbohydrate (by difference) 66.5%.

Vitamins and Minerals	Per 100 Gm.
Thiamine	1.1 mg.
Riboflavin	1.1 mg.
Ascorbic acid	33 mg.
Niacin	11 mg.
Calcium Pantothenate	4.4 mg.
Choline Bitartrate	55 mg.
Vitamin A	550 I. U.
Vitamin B ₁₂	0.44 mcg.
Folic acid	0.28 mg.
Pyridoxine HCl	0.55 mg.
Vitamin D	55 I. U.

Calories.—3.9 per gram; 110.6 per ounce.

Use.—A dietary supplement for oral use or tube feeding.

Gerber Products Company, Fremont, Mich.

Gerber's Strained Egg Yolks

This product consists of egg yolks and salt in water necessary for preparation and has been processed for 45 minutes at 240 F.

Analysis (submitted by manufacturer).—Total solids 29.38%, moisture 70.62%, ash 1.25%, fat (acid hydrolysis) 17.16%, crude fiber none, protein ($N \times 6.25$) 9.59%, and carbohydrates other than crude fiber (by difference) 1.38%.

Vitamins and Minerals	Per 100 Gm.
Vitamin A	640 I. U.
Beta Carotene	230 I. U.
Thiamine	0.106 mg.
Riboflavin	0.236 mg.
Ascorbic Acid	0.227 mg.
Niacin	Trace
Calcium	84 mg.
Phosphorus	173 mg.
Iron	5 mg.
Sulfur	0.003 mg.

Calories.—1.98 per gram; 56 per ounce.

Use.—For use in the feeding of infants and young children and in special diets.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

APPARATUS ACCEPTED

The following additional product has been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

RALPH E. DE FOREST, M.D., Secretary.

Otarion Hearing Aid, Model B-15

Otarion, Inc., 4757 Ravenswood Ave., Chicago 40.

The Otarion Hearing Aid, Model B-15, uses three vacuum tubes, one 1.5 volt mercury type A-battery, and one 15 volt B-battery. The body of the instrument measures 62 by 45 by 22 mm. and weighs 70 gm. With batteries, earphone, and receiver cord the total weight is 108.5 gm. Evidence indicating sound construction and satisfactory performance was obtained by the Council.

Otarion Hearing Aid,
Model B-15

TESTS OF THYROID ACTIVITY

Although the use of radioactive tracer elements in the diagnosis of thyroid function has raised the question whether the basal metabolic rate (BMR) is obsolete, the new test may be expected to supplement rather than to supplant the older test.¹ To prevent the needless performance of a whole battery of thyroid function tests on every suspect the clinician should select the test(s) likely to be most informative regarding a given patient. In frankly hypothyroid or hyperthyroid patients the BMR is superior to determining the uptake of radioactive iodine by the thyroid but is subject to wide variations in euthyroid persons.² The tracer test is, therefore, most useful in evaluating borderline conditions.

Serum cholesterol determinations are of value only in diagnosing hypothyroidism, which is associated with abnormally high levels. Determination of the protein-bound iodine (PBI) in the serum correlates well with the tracer test, but in patients with hypothyroidism the tracer test is more sensitive. Although some believe the PBI test to be better than the BMR, the technique is not easy, and unless it is performed by a technician of known ability the results are likely to be unreliable. It is also unreliable in any patient who has ever had a sinus tract injected with iodized oil (Lipiodol) and in any patient who has ingested gallbladder dye within six months preceding the test.

The development of the gamma-detecting scintillation counter has made possible the use of radioiodine in amounts as low as 1 μ c or one hundredth of the usual dose. This makes it possible to obtain a recheck if necessary without exceeding a safe dose. Technicians can be easily trained to perform the tracer test, but, although capsules of radioiodine are now commercially available and their use requires no special monitoring, the test should be done only in clinics specializing in the treatment of thyroid diseases. In euthyroid persons the uptake in the thyroid is complete in 24 hours and amounts to about 30% of the tracer elements; in hypothyroid patients complete uptake takes a little longer and amounts to

about 10%; and in hyperthyroid patients complete uptake takes less time and amounts to about 70%. The tracer test has the advantage over the BMR that the cooperation of the patient is not required and no preliminary rest period is necessary. Nervousness and hypertension both elevate the BMR but do not affect the tracer test. A fair percentage of patients with severe toxic nodular goiter give a normal tracer test, and in this type of patient the BMR is more accurate. The tracer test is not valid if the patient is taking iodine in any form, and it must be remembered that iodine is present in some vitamin mixtures. Interference with the test following the ingestion of gallbladder dyes persists for about one week, following the administration of iodopyracet (Diodrast) for two weeks, and following the use of iodized oil (Lipiodol) for a longer time. The test should not be given until a few days have elapsed after the withdrawal of desiccated thyroid.

Determination of the percentage of radioiodine excreted in the urine in 24 hours is almost as accurate a test as determination of the uptake in the thyroid. Tracer testing is absolutely necessary before treatment with radioiodine. It may be concluded that, although the tracer test has not rendered the BMR obsolete, it is an accurate, sensitive, practical, safe, and rapid test of great value in properly selected cases.

USE OF STANDARD NOMENCLATURE

One of the best and most helpful publications of the American Medical Association is its "Standard Nomenclature of Diseases and Operations." It provides a way of setting up records so that meaningful statistics can be compiled, hospital records are easily understood by all who read them, and physicians can understand what others are talking about when diseases and operations are mentioned. This book has had a profound effect on medical teaching, medical writing, and the keeping of medical records. Some indication of its reception and employment lies in the figures concerning its use. "Standard Nomenclature of Diseases and Operations" is used in 91% of federal hospitals, 85% of more than 300 new Hill-Burton hospitals, and 74% of all hospitals in the United States. There seems to be a direct relation between size of hospital and use of this book; the larger the hospital in terms of beds the more widely used the book.

The purpose of any disease index is to provide a record of data relating to specific diseases. The use of the data determines the method of application of the nomenclature. The coding in Standard Nomenclature may be simplified, expanded, or adjusted to meet the needs. Frequency of referral and type of requests that result in the use of the file will determine which method is most suitable for the institution. Of the Hill-Burton hospitals, 60% are using Standard Nomenclature in its simplified form. In 65% of these hospitals the coding is being done by the record librarian, in 15% by physicians, and in 20% by other hospital personnel.

1. Seed, L.: Is the B. M. R. Obsolete? *Illinois M. J.* 104: 113-117 (Aug.) 1953.

2. Barrett, T. F., and others: Evaluation of a Thyroid Panel: Practical Application of Scintillation Counter in Diagnosis of Diseases of the Thyroid, *J. A. M. A.* 152: 1414-1417 (Aug. 8) 1953.

Proper orientation of all personnel who code diseases and operations according to Standard Nomenclature is an important step. The purpose and the value of the index should be presented, and the person who is coding must have a working knowledge of the nomenclature as well as being conversant with the basic principles. These are not difficult requirements, and their application in all hospitals would mean much for everyone, from researcher to hospital administrator, from practitioner to record librarian, and from student to teacher.

VITAL STATISTICS AND MEDICAL RESEARCH

A physician experiences a renewed feeling of satisfaction whenever data from any source reveal further manifestations of the lengthening of the average human life. Although every scientist and engineer, and in fact every productive worker in industry and agriculture, can claim some credit for the improved standards of living that have brought this about, the physician deals with the immediate problems of birth, sickness, and death and feels that he is making an especially direct contribution to a noble cause.

Medical progress is fortunately measurable in figures for morbidity and mortality. Efforts to measure progress in other fields, and to assess the accomplishments of social agencies such as national governments and supranational economic organizations, lead directly to the difficult problem of quantitatively evaluating such things as happiness, culture, good will, and freedom. Moreover, if progress in political science is measured in terms, say of soldiers killed in combat, or of civilians displaced, starved, or exterminated in the world's recent history of blockades, bombings, and invasions, the figures are embarrassing, for they ought to be decreasing, not increasing. One is tempted to conclude that medical progress has been more substantial than political progress. In any case, comparisons are most easily made in terms of numbers, and a constant keeping of statistics is essential if progress is to be measured and continued.

It was regretted by many that the League of Nations, which put itself out of existence at a last meeting on April 18, 1946, in Geneva, received so little popular recognition for the medical aspects of its work. Its political failures were discussed in merciless detail after every crisis; its steady, substantial work in mapping the distribution of disease and detecting the outbreaks of epidemics was not equally publicized.

These reflections are prompted by two impressive articles in a recent number of the *British Medical Journal*. The first¹ is the presidential address, by Sir Russell Brain, to the First World Health Organization International Congress on Health and Vital Statistics, in which he points out that in respect to health the world today is a single community. "Infection," he says, "can now spread in a few days from one end of the world to the other, and may thus enter a country in which, as a result of their bacteriological history, the inhabitants possess a poor immunity to the invader." The international

activities relating to health begun by the League of Nations now seem more important than ever and must be continued by the World Medical Association and the World Health Organization.

Unfortunately, Sir Russell observes, the work of preventive medicine, especially the work with statistics, is not easily glamorized. A youthful motion picture audience is fascinated by the picture of a surgeon in the operating room or of a psychiatrist quieting a disturbed patient, but it takes more mature minds to appreciate the importance, the tensions, and the occasionally exciting discoveries in vital statistics. Yet it is to this painstaking application of mathematics that we must look for constant guidance in efforts to prevent disease and increase well-being.

Sir Russell's remarks are aptly followed in the *British Medical Journal* by a statistical paper by Colin White² with the typically unglamorous title "Sampling in Medical Research." Readers who have learned from experience what explosive material can come in such packages will not be deterred by the title and are rewarded by a lively discussion of fallacies arising from biased methods of sampling. Authors of clinical papers need to be aware of the kind of bias that may enter into hospital statistics, into postmortem data, and into series of surgical histories. Examples are given, especially of the "fallacy of the interesting case." Exceptional patients "provide welcome relief from the dullness of examining a series composed mainly of normal people," but they are likely to involve the unwary investigator in a phenomenon called by Galton, more than half a century ago, regression toward the mean. Many physiological measurements like blood pressure and metabolic rate fluctuate from hour to hour, from day to day, and the persons who happen to have the highest or lowest values at any given moment are very likely to be found nearer the average next time they are observed. Anything whatever done in the interval between observations will appear to have had a "normalizing" effect on the extreme cases. This phenomenon has been rediscovered independently by other investigators trying to account for odd therapeutic results and has been perhaps more appropriately renamed centripetal drift. White shows how this phenomenon explains the results of administering iron and regulating the diet in supposed cases of anemia in pregnancy.

The outstanding investigation in which the question of bias arises is that of Kinsey and his associates.³ Many readers feel they must choose between the suppositions either that the women interviewed by Kinsey were exceptionally mendacious or that they were shamefully abandoned, and a recent writer in a midwestern American weekly was so distressed by this dilemma that he frankly stated he was writing his review without having read the book. This exhibition of squeamishness makes one won-

2. White, C.: Sampling in Medical Research, *Brit. M. J.* 2:1284-1288 (Dec. 12) 1953.

3. Kinsey, A. C.; Pomeroy, W. B.; Martin, C. E., and Gebhard, P. H.: *Sexual Behavior in the Human Female*, Philadelphia, W. B. Saunders Company, 1953.

der what would happen in hospitals if laboratory technicians suddenly refused to examine some of the materials they receive every day. In the present case the question is, of course, what kinds of bias may have affected Kinsey's results, and in what respects his conclusions must be qualified. White takes up this aspect of Kinsey's work, with other examples as well, and shows how such procedures as random selection can prevent mistakes.

If the "fallacy of the interesting case" is to be avoided, the study of the usual must be carried on as carefully as that of the unusual. The physician makes an indispensable contribution each time he fills out a birth or death certificate. Older citizens recall the embarrassments, exasperating correspondence, and costly delays that have been known to result, in the past, from the occasional failure of old-time physicians to report births, for instance. The modern physician realizes how essential it is to be prompt and conscientious in such matters, and the gradual extension of the registration area of this country until every state was included makes inspiring history.

DIAMIDINE THERAPY OF BLASTOMYCOSIS

Blastomycosis is a serious infection caused by the fungus *Blastomyces dermatitidis* and confined chiefly to the North American continent. While the cutaneous form of the disease often appears to respond to iodides, x-ray treatment, or surgical excision, the systemic form has proved notoriously resistant to therapy. Great interest, therefore, is attached to the numerous reports on the successful treatment of both cutaneous and systemic blastomycosis by certain aromatic diamidine compounds.¹

The clinical trial of diamidine derivatives in blastomycosis was prompted by a report by Elson in 1945 that a number of fungi, including *Blastomyces dermatitidis*, were inhibited *in vitro* by propamidine.² Propamidine and the more effective but more toxic stilbamidine are members of a series of aromatic diamidine compounds synthesized about 15 years ago by British scientists after it was shown that a related but highly toxic compound, decamethylenediguanidine dihydrochloride (Synthalin), had marked trypanocidal activity. Both propamidine and stilbamidine are effective in the treatment of trypanosomiasis and leishmaniasis, though their toxicity has restricted their use particularly in the latter condition.³

In discussing the toxic potentialities of the diamidines, much emphasis is placed on the necessity of employing freshly prepared solutions only. These drugs are unstable in aqueous solution, especially in the presence of sunlight, and break down to give toxic products. Many of the earlier reported toxic effects occurred with solutions prepared some time before use.⁴ The immediate toxic effect of the aromatic diamidines consists of circulatory collapse, which, however, can be largely obviated by administration by slow intravenous drip. It is questionable whether late hepatic or renal damage arise from therapeutic doses of freshly prepared solutions; however, the toxicity of these compounds may be enhanced in the

presence of hepatic or renal disease, and they should be used cautiously if at all under such conditions.

A curious late manifestation of diamidine toxicity is the development of fifth cranial nerve neuropathy, apparently reversible, and manifested by paresthesia, hypalgesia, and anesthesia over the region supplied by the trigeminal nerve. This effect is reminiscent of that which may follow exposure to trichloroethylene. Like trichloroethylene, stilbamidine has been reported to give relief in tic douloureux.⁵ Toxic psychosis has been reported following stilbamidine therapy; however, the patient was emotionally disturbed prior to administration of the drug.⁶

Recently, Snapper has reported on the use of 2-hydroxystilbamidine in blastomycosis.⁷ Previous work had led him to conclude that this compound is more stable in solution than stilbamidine and does not produce trigeminal neuropathy. Encouraging improvement was reported in three cases of systemic blastomycosis and one case of the cutaneous form of the disease. No untoward effects were noted other than a transitory weakness, dizziness, and hypotension in one patient after rapid injection of the drug.

The effect of the aromatic diamidines in other systemic fungus infections is under study. *In vitro* studies suggest that these compounds have quite a wide spectrum of activity.⁸ Preliminary clinical reports indicate they may be of value in actinomycosis,⁹ nocardiosis,¹⁰ and sporotrichosis.¹⁰ Future work will doubtless be directed toward expanding the field of usefulness of these drugs and to the development of more effective and less toxic derivatives.

ORGANIZATION SECTION

STATEMENT OF DR. WALTER B. MARTIN TO HOUSE COMMITTEE ON INTERSTATE AND FOREIGN AFFAIRS

I am Dr. Walter B. Martin of Norfolk, Va., where I am engaged in the active practice of medicine. I am President-Elect and a member of the Board of Trustees of the American Medical Association. I am appearing here today with Dr. Louis H. Bauer, New York City, immediate Past President of the Association, Dr. David B. Allman, Atlantic City, N. J., Chairman of our Committee on Legislation, Dr. George F. Lull, Secretary and General Manager of the American Medical Association, and several members of our staff. We are here at the invitation of your committee to participate in the general health inquiry which you have been conducting for the past several months.

As you know, the President of our Association, Dr. Edward J. McCormick of Toledo, Ohio, testified briefly before your group on Oct. 1 and reviewed the activities of the American Medical Association in the field of medical research. Since his appearance, many individuals and organizations have presented their views concerning the condition of the nation's health. Frequently, in their testimony these individuals and organizations have decried the many inadequacies in this country's over-all medical and health picture.

The American Medical Association would be the first to admit that despite the remarkable record of medical achievements much remains to be accomplished. In practically every instance of recognized deficiency, the A. M. A. has also been the first organization to undertake a positive, constructive program of action. We know full well that certain medical scientific mysteries still must be solved. We are aware that in some areas problems of inadequate supply or improper distribution of medical personnel and facilities exist. We also realize that the best of medical care should be made available to all our citizens, regardless of their economic status, and that every effort should be made to alleviate the financial burden imposed by long-term illness.

We feel, however, that in an effort to create public sentiment in support of a government-controlled medical care program, a distorted picture of the health and medical situation in this country has been drawn. At times the magnitude of such problems has been exaggerated while actual progress toward solving them has been minimized. To lose perspective is to lose judgment. For this reason we would like to clarify certain misconceptions which have arisen in regard to the nation's health and medical needs.

Many of those who testified before this committee indicated that increased medical costs were proving financially disastrous to families faced with illness or accidents. Medical costs—like all other costs—have risen in the last few years. Statistics presented by the United States Department of Labor for the third quarter of 1952, however, revealed that living costs had increased 90.8 per cent since 1935-1939 while medical costs had increased only 65.5 per cent in the same period. Between 1935-1939 and 1950 average weekly wages rose 165 per cent while physicians' fees climbed only 48 per cent. As a result, the average person works only 60 per cent as long today to pay for the same amount of medical services.

New techniques and new drugs enable physicians to shorten length of illness and reduce hospital stays as well as wage loss. As a result, the total medical bill for many illnesses often actually is less than it was 15 years ago.

Proof that the cost of medical care presents no great problem to the majority of American families was given in a survey completed for the Federal Reserve Board last year. Of about 53,000,000 families in the United States, almost 43,000,000—over 80 per cent—reported no medical debts whatsoever. One million families owed from \$200 to \$1,000, while another 200,000 owed more than \$1,000. That would indicate that less

than 3 per cent of all the people in the survey need help to pay their medical bills. The remaining 9,000,000 families were listed as in debt for medical expenses in amounts varying from \$1.00 to \$200.

Some critics point to the increasing death rate from heart disease and cancer as an indication of a medical crisis. Actually, this is a heartening sign of great medical progress. The median age at death in the United States has jumped from 30 to 66 years. Twenty years from now, although the death rate from certain diseases in our aging population may be higher, the length of life will be greater and the mortality rate for each age will be lower. Health progress and the number of deaths each successive year are simply two different ideas. A physician can never conquer death—he can only postpone it. Persons who are saved by medical advances and skills from death at an early age later fall victim to the degenerative diseases which now appear to be increasing.

A serious shortage of doctors has been alleged. Actually, we have more doctors than any other nation, and we have more in proportion to population than any other country except Israel, which has an abnormal influx of refugee physicians from Europe. For more than twenty years the supply of doctors has been increasing at a faster rate than the general population. It is estimated that the period of 1950-1960 will bring another 30 per cent increase in the supply of physicians.

Today we have a total of 220,104 physicians—the largest in our history. Of this number 159,120 are in active practice. All the rest, except for about 9,700 who are retired or not in practice, are serving American health needs in research, teaching, hospitals and government service. On the basis of an estimated population of 160,000,000 in 1953, we now have one physician for every 727 persons, or approximately one physician actually engaged in the practice of medicine for every 1,000 persons.

For the fifth consecutive year, the total number of students enrolled in approved medical schools has established a new record. The number of students graduated constitutes the largest group ever graduated in one academic year. Enrollments in the country's 72 medical and seven basic science schools during 1952-1953 totalled 27,688, or 2.3 per cent more than the 27,076 enrolled during 1951-1952. The estimated number of graduates for 1953-1954 based on enrollments reported for senior classes in schools, is even greater—6,831—than last year (6,668) which exceeded by 279, or 4.4 per cent, the previous record established in 1947, when at the termination of the wartime accelerated program several schools graduated more than one class.

It is obvious that in the areas of medical progress, medical cost and doctor supply the picture is far brighter than some would have you believe. We hope that we have clarified some of these misconceptions.

For more than a hundred years the American Medical Association has been dedicated "to the promotion of the science and art of medicine and the betterment of public health." Our devotion to these principles has not taken the form of mere lip service, but rather of concrete, constructive programs designed to bring better health to the American people.

The record of American medicine's achievements in elevating the standards of medical education, fighting medical quackery, maintaining ethical standards of medical practice and safeguarding health through the evaluation of drugs, foods, physical devices and techniques as well as in the areas of school, rural and industrial health is an outstanding one. We would like to reiterate for this committee in as brief a fashion as possible our Association's specific efforts to provide the best of medical services and facilities and to distribute them equitably throughout the nation.

1. *On Behalf of Medical Progress.*—Medicine has come a long way down the medical progress road in a fantastically short time. Today America is the healthiest large nation in the world. Babies born today can expect to live at least twenty years longer than those born in 1900. Women can face child-

birth with little or no fear, for the chances of surviving pregnancy, childbirth and confinement are better in the United States as a whole than 999 out of 1,000. The dread diseases that once were killers—typhoid fever, smallpox, diphtheria, pneumonia and many others—have been brought under control.

Since 1900, while our total population has more than doubled, the number of persons 65 years of age or older has more than quadrupled. This accounts largely for the marked rise in the death rates for heart disease, cancer and other diseases of old age.

Within a few decades vitamins, sulfa drugs, the antibiotics and hormones have been added to the physician's armamentarium against disease. American surgeons today are performing delicate, life-saving operations on the heart, lungs, brain, stomach, kidneys and other vital organs which just a few short years ago would have been impossible.

The past two years have brought heartening advances in the battle against infantile paralysis. News of successful trials of gamma globulin from human blood was followed with announcements indicating that the next two or three years may bring a vaccine effective against poliomyelitis.

More recently, medicine has harnessed byproducts of the atomic age called radioisotopes to kill certain forms of cancer and to trace vital body functions. While the basic cause or causes of cancer or any one specific cure has not been discovered, the early diagnosis of the disease and its surgical or radiation treatment has resulted in the cure of many cases. New methods of treatment have been evolved with drugs and atom-smashing machines. The whole field of atomic medicine may pave the way to new and startlingly significant medical discoveries.

It is also estimated that the efficiency of the average physician has increased about 30 per cent in the past 15 years. This has come about through the use of new drugs and antibiotics, new or improved techniques, modern equipment, increased auxiliary help from laboratories and technicians, improved transportation and communication and better coordination of all medical facilities.

2. On Behalf of Medical Education.—The high standards of medical education in the United States have resulted directly from the medical profession's efforts over the past 50 years to protect the public against unqualified, poorly trained doctors. Today, all of the nation's 79 medical schools are approved institutions which meet high requirements involving their teaching staffs, curricula, classroom and clinical facilities, hospital teaching programs and all-over educational policies. Two additional schools, University of Miami and University of California in Los Angeles, have medical schools which have not yet graduated their first class. Another medical school in New York is contemplated, to begin operation in 1955. In addition, high standards also have been established for the approval of intern and residency training programs in hospitals, and a growing emphasis has been placed upon postgraduate education and refresher courses to keep physicians abreast of the latest medical developments. During 1953, for example, a total of almost 1,600 postgraduate courses was offered by the nation's medical schools, medical societies, hospitals and other health agencies. A. M. A.'s two scientific meetings each year, coupled with the meetings of the various specialty groups, offer American physicians the most complete postgraduate study opportunities in the world.

A. M. A. also helps elevate standards in auxiliary fields of medicine by approving upon request schools for laboratory technicians, occupational therapists and other allied fields.

To assure an increasing supply of physicians in this country the American Medical Association has actively encouraged expansion of medical schools and facilities and the development of new medical schools in certain areas. This increase in enrollments, the expansion of teaching programs and the rising costs of operation since World War II have created major financial problems in some of our medical schools.

In the spring of 1949 medical leaders and others sponsored the establishment of the National Fund for Medical Education, whose purpose is to raise unrestricted funds annually on a national scale from voluntary sources for the support of medical schools. In 1950 the American Medical Association set up the American Medical Education Foundation to raise funds

from individual physicians and medical groups. The success of this endeavor is told in these figures: At the end of 1953 the American Medical Education Foundation recorded a gross return of \$1,089,962. The American Medical Association has given an additional \$2,000,000 in four successive grants to this project since 1950. The National Fund for Medical Education in its three year history has contributed \$4,764,152 to the nation's medical schools.

Medical schools report that these grants have enabled them to secure additional teachers, retain others by providing urgently needed salary increases, purchase teaching equipment and rehabilitate or expand teaching facilities.

We are convinced that federal financial assistance to the medical schools for operating purposes is not desirable. The medical schools still need money, however, and we propose:

(a) Increased efforts to raise voluntary funds through the American Medical Education Foundation and the National Fund for Medical Education.

(b) Adoption of legislation authorizing one-time federal grants for construction and renovation of the physical plant of medical schools.

3. On Behalf of Better Doctor Distribution.—Because many problems of so-called doctor shortage are in reality problems related to physician maldistribution, the American Medical Association has established a placement bureau to serve as a clearing house for information in answer to requests from physicians seeking a location and from communities seeking a physician. Placement programs are now in active operation in at least 37 states, and at least 32 are sponsored by state medical societies. The A. M. A. is sponsoring rural health conferences and programs and preparing literature to help communities attract physicians in an effort to stimulate public as well as medical efforts to bring doctors into needed areas.

4. On Behalf of Allied Health Personnel.—Problems of health personnel resources are not problems of physician-supply alone. The American Medical Association has for some time been concerned over the existing nurse shortage and in June 1947 appointed a committee to study and report on this problem. On the basis of this report and on subsequent information obtained from the official nursing associations we have concluded that in certain areas there is a need for construction of new nursing schools and for the modernization of existing facilities. Although the problem is fundamentally a local one which each state should solve on the basis of its individual needs, the American Medical Association favors legislation embodying:

(1) One-time federal grants-in-aid to states, based on the Hill-Burton Act formula and administrative machinery, for construction, equipment and renovation of the physical plants of nursing schools, on a matching basis, with no part of the funds to be used in any manner for operational expenses or salaries;

(2) Grant of federal funds to the Committee on Careers in Nursing or some comparable private agency to help support a nurse recruitment program; and

(3) A temporary grant-in-aid program, not to exceed five years and administered by the states, to provide scholarships for advanced nursing education to aid in the development of a larger corps of teachers.

We believe that these suggestions would meet the current need and at the same time safeguard the freedom and independence of educational institutions.

5. On Behalf of Increased Hospital Facilities.—Without proper facilities physicians and allied health personnel are unable to operate at peak efficiency. The increased community interest in health problems in general has been reflected in the construction of an amazing number of community hospitals. Many have been planned and financed completely with private or tax funds at the local level; others have been built with the assistance of the federal government.

The American Medical Association has continually supported the Hospital Survey and Construction Act, more familiarly known as the Hill-Burton Act, which became law in August 1946. Since the approval of the first projects in fiscal year 1948, over a billion dollars has been spent by the federal govern-

ment, states and communities in the construction of hospitals under this program. In future construction of health facilities, particular attention should be given to institutions for the chronically ill. We believe these should be constructed contiguous to or in connection with general hospitals.

The American Medical Association not only favors federal legislation for hospital construction but is energetically working to raise standards of existing hospital facilities. We are an active member of the Joint Commission on the Accreditation of Hospitals, along with the American College of Physicians, the American College of Surgeons, the American Hospital Association and the Canadian Medical Association. This is a private organization designed to conduct an inspection and accreditation program which will encourage physicians and hospitals voluntarily to (1) apply basic principles of organization and administration for efficient patient care; (2) promote high quality medical and hospital care in all its aspects; and (3) maintain the essential diagnostic and therapeutic services in the hospital through coordinated effort of the organized medical staff and the governing board of the hospital.

6. On Behalf of Solving the Economic Problems of Medicine.—We must consider two groups of individuals when discussing the problems of the cost of medical care: (1) those who are able to pay normal costs of medical care and (2) those who require assistance in meeting their medical bills. For those who are willing and able to meet their obligations, the medical profession has been carrying on the following positive program:

(1) **Continued Promotion of Voluntary Health Insurance:** The American Medical Association believes that voluntary health insurance provides one of the best methods by which the average American can finance a substantial portion of his medical and health costs.

For years we have advocated and strongly promoted the sale of voluntary health insurance as one of the aids to cushion the economic shock of illness. The growth of voluntary health insurance, which embraces benefits for hospital, surgical and medical expense, has been phenomenal during the past few years. By Jan. 1, 1953, nearly 92 million Americans had some form of hospital expense benefit insurance. At that same time over 73 million were protected by some form of insurance against the cost of surgical care and nearly 36 million persons had coverage providing some medical expense benefits in addition to surgery. This amazing progress has been achieved without benefit of government subsidy.

The problem of providing economic protection against "catastrophic illness"—any illness, acute or chronic, the financial impact of which seriously disrupts the family budget—is now receiving ever increasing study and experimentation by several agencies in both the private and nonprofit fields.

To meet the costs of extended illness or injuries which the average man cannot afford to pay, a number of private and non-profit companies are now writing "major medical expense" insurance, sometimes called catastrophic coverage or medical disaster insurance. Such policies are designed to cover cases of extended disability, those which are relatively infrequent, but financially severe. Generous amounts of maximum benefits, ranging from \$2,500 to \$10,000, are provided, and most policies provide for reimbursement of expenses in excess of a minimum deductible amount which ranges from \$100 to \$500. In many instances some basic programs provide benefits which fulfill a substantial portion of the deductible amount under these policies.

Another principle followed generally in major medical expense insurance policies is the use of a co-insurance provision. A percentage, between 70 and 80 per cent, of the expense in excess of the deductible amount is reimbursed, making the insured person a co-insurer to the extent of the balance of the expenses. Many who are familiar with this class of insurance feel that the insured person must have a financial interest in all health expenditures to the end that there will be less tendency to demand services which may not be necessary.

Major medical expense policies are still in the experimental stage, but at the end of 1953 more than a million persons were covered by these policies and the numbers are increasing rapidly.

The past 10 to 15 years of constructive advances in the field of voluntary health insurance have shown that: The great majority of American people do want to pay their own way. It is desirable that the individual should participate in the cost of his illness for the purpose of reducing long-stay and abuses. A certain amount of medical care is an expectable item on any family budget. For this reason the promotion of the benefits that are comprehensive is not sound because it is the need for protection against the financial impact of truly major sickness or injury that must be emphasized.

(2) **Policing Its Own Ranks:** Every medical society in the country has been urged by the American Medical Association to crack down firmly on any physician who charges exorbitant fees.

(3) **Establishing Mediation Committees:** In all professions, friction sometimes arises between the professional members and those they serve. The medical profession has established mediation, or grievance, committees to hear and fairly resolve complaints against physicians in regard to fees or care provided. Evidence of local societies' concern for the patient's satisfaction is the fact that nearly 500 medical societies now operate such committees.

(4) **Encouraging Fee Discussions:** Misunderstanding is often the basis for complaints about the cost of medical care. In many cases, when patients talk over expenditures with their doctors, friction disappears. For this reason A. M. A. has been encouraging physicians to estimate in advance with patients not only medical charges but hospital, drug and other costs involved in illness.

(5) **Stimulating Good Business Practices:** To reduce fee misunderstandings the American Medical Association urges all physicians to itemize medical bills and to follow orderly business procedures in submitting medical bills.

Since time immemorial, the physician has been called upon to render professional services to the indigent without compensation. Every doctor spends a proportion of his working hours dispensing free medical care. The dollar value of these services is considerable but cannot be estimated with accuracy.

Because protests have been made at various times that medical care is being denied certain individuals because of its cost, the American Medical Association in 1952 urged its societies to undertake energetic campaigns to organize and vigorously promote programs which at the county level offer to provide services of a physician to anyone unable to pay. Such programs have been highly successful. It is necessary to bring such programs to the attention of the public, because in many instances the public is not aware that medical service is available locally without cost to those unable to pay.

In addition to setting up the mechanisms to provide medical care to all, regardless of ability to pay, 577 county medical societies are taking an active part in providing medical care for indigent citizens in cooperation with state and county authorities.

There are two groups of individuals who are unable to meet the cost of illness at the time it occurs—the frankly indigent and the medically indigent.

The indigent are dependent on outside assistance for the basic necessities of life. The American Medical Association believes that the medical care of this group is a local and state government responsibility. No program of health insurance is practical for this group since they are unable to purchase it. We believe that direct payment at the time of illness for this group is the most practicable and economic approach.

The medically indigent are normally able to meet the cost of their daily needs and to purchase health insurance. They are, however, unable to meet the cost of illness when it occurs. This group can be reduced by educating them in the necessity of giving health protection priority in their expenditures. However, when illness occurs, they require aid by direct payment of their health costs from local and state funds.

We are carrying on through personal field visits studies of successful local indigent medical care plans with the purpose of extending adequate care to all persons who are indigent and to the borderline group which we call the medically indigent. From the findings we expect to obtain useful data that will aid in the solution of this very difficult problem.

In view of the progress being made toward solving our health problems we have reasons for encouragement but not complacency. The American Medical Association has always accepted and carried out the responsibility of leadership in safeguarding the public health, raising the standards of medicine and making good medical care available to the people.

This nation's medical progress over the past half century has given the United States the world's highest standards of health and medical care and has made it the world center of medical education and research. That progress has been achieved under a voluntary system which emphasizes free enterprise, individual initiative and responsibility, and cooperative effort. It has been accomplished not by physicians alone but with the help and cooperation of allied professions, many branches of science, nurses, hospitals, business, industry, education and all segments of American society.

Our most urgent effort should now be directed to the solution of the problem of the medically indigent and the chronically ill. We believe that this objective can be reached without major change in our existing mechanism.

FEDERAL MEDICAL LEGISLATION

Health Services Reinsurance

Congressman Wolverton (R., N. J.) in H. R. 6949 would create an independent federal health reinsurance corporation and authorize a 50 million dollar appropriation with which to start reinsurance of nonprofit health plans against losses over \$1,000, thus encouraging them to write unlimited coverage. The federal corporation would repay the health plan two-thirds of the claims in excess of \$1,000 paid in any 12 months. Premiums charged for reinsurance health service contracts would be 2% of the total gross payments received by the health service association. Three directors would be appointed for six year terms by the President of the United States and would be confirmed in the Senate. The health plan would be required to limit its out-of-state subscribers to 25% of the total membership and would have to accept nongroup applicants. The physicians and hospitals would have to agree to limit any additional charges to 25% of any established fee schedule.

Under the proposed plan, premiums would be based on the subscriber's income. No participating health plan would be permitted to pay its subscribers in cash benefits. Subscribers to health plans would be covered up to 75% on the cost of the first 12 visits by licensed physicians and up to 95% on the cost of all benefits on medical care contracts. Operating expenses of the federal corporation would be covered, when necessary, by appropriations from Congress. Health service associations would have the right to appeal federal corporation decisions to the U. S. Circuit Court of Appeals. This measure is not the President's reinsurance bill, which has not as yet been introduced. This bill is similar to H. R. 8746, introduced by Mr. Wolverton, June 7, 1950. The new bill was referred to the Interstate and Foreign Commerce Committee.

Loans for Construction of Medical Facilities

Congressman Wolverton (R., N. J.) would amend the Hill-Burton Hospital Construction Act, by H. R. 6951, to provide mortgage loans insurance similar to Federal Housing Administration loans, to stimulate private investment for the construction of medical facilities. The bill requires at least 75% of any facility for which an insured loan is granted to be devoted to members of a group participating in a prepayment health plan. Banks, investment houses, physicians, and other groups could apply to the Surgeon General for insurance on loans for medical centers, hospitals, clinics, doctors' offices, and other facilities. Mortgages could not exceed 5 million dollars and would have to be paid back within 25 years, with interest rates set at 5% or less. Similar measures were introduced in the previous session of Congress. This bill was referred to the Interstate and Foreign Commerce Committee.

The summary of federal legislation was prepared by the Washington Office of the American Medical Association and the summary of state legislation by the Bureau of Legal Medicine and Legislation.

Loans to Nonprofit Health Associations

In H. R. 6950, Congressman Wolverton (R., N. J.) proposes authorization for an appropriation of 5 million dollars a year for the next two fiscal years and 10 million dollars a year for the next three succeeding fiscal years, or a total of 40 million dollars over a five year period for long-term, interest-bearing loans to assist voluntary nonprofit health service associations in obtaining facilities and equipment. To obtain a loan, the association would submit to the Surgeon General of the U. S. Public Health Service evidence of (1) control of the practice of medicine and dentistry solely by duly licensed members of the professions involved, (2) control of the general administration of the plan by a governing board, "a majority of whose members shall be persons who do not themselves furnish, or represent other persons that furnish health services," (3) satisfactory compensation to participating physicians and the governing board, (4) voluntary participation in the plan by beneficiary members and by physicians, and (5) agreement by the plan to render services in case of emergency to any resident of any community whether or not they are members of the plan.

The National Health Services Facilities Council of 14 members would formulate standards with the Surgeon General for making loans to eligible health service plans. The council would consist of 1 representative each, of the Department of Labor and the Department of Agriculture, and 12 members appointed for four year terms by the Surgeon General. Three would represent "operating non-profit prepaid medical service plans." Three would be representatives of bona fide national farm programs, and three would be representatives of bona fide national labor organizations, and three would be members of the medical, dental, and nursing professions. This bill was referred to the Interstate and Foreign Commerce Committee.

Deduction of Health Insurance Plans

Congressman Wolverton (R., N. J.) in H. R. 6952 would amend the Internal Revenue Code to permit the deduction of "certain payments for health insurance without regard to the 5 per centum limitation" placed on medical expenses above which deductions may be made from income in calculating income tax. There are a number of similar bills already before the 83rd Congress. This bill was referred to the Ways and Means Committee.

Social Security Extension

Congressman Curtis (R., Neb.) in H. R. 6863 would extend Old Age and Survivors Insurance to about 5 million more already retired aged persons. Mr. Curtis, chairman of the Subcommittee Investigating Social Security Programs, states that this bill represents his personal opinions on social security, not those of the administration. Coverage would also be extended to almost all occupations, including the medical profession, not now covered. The coverage provisions are virtually identical with the previously reported administration's H. R. 6812, introduced Aug. 3, 1953, by Congressman Daniel Reed, chairman of the Committee on Ways and Means. The Curtis bill would retain the present wage relation benefit provisions by (1) continuing the monthly payments up to the present maximum of \$85, (2) increasing the monthly benefits to \$45 for all those who are not now receiving that amount, (3) maintaining the contributory principle of the present law, and (4) continuing the present trust plan. The present limit of \$75 a month maximum earnings, for persons under social security, would be increased to a total of \$1,000 annually instead of being computed on a monthly basis. The bill also provides that payments to the social security fund would be discontinued when a retired worker reaches 66 years and has paid for 40 quarters of coverage. This bill was referred to the Ways and Means Committee.

Lengthening Presumption-of-Service-Connection Period for Arthritis

In H. R. 6867, Congressman Ayres (R., Ohio) proposes "to amend the veterans regulations to provide that arthritis developing a ten per centum or more degree of disability within three years after separation from active service shall be pre-

sumed to be service-connected." The present period is for one year. This bill was referred to the Committee on Veterans' Affairs.

Lengthening Presumption-of-Service-Connection Period for Active Tuberculosis, Multiple Sclerosis, and the Chronic Functional Psychoses

Congresswoman Rogers by H. R. 6931 would "amend veterans regulations to establish for persons who served in the Armed Forces during World War II a further presumption of service connection for multiple sclerosis and the chronic functional psychoses . . . and active pulmonary tuberculosis or all other types of active tuberculosis . . . developing a 10 per centum degree of disability or more within three years from the date of separation from active service." This bill is almost identical with H. R. 33 introduced by Mrs. Rogers in January, 1953, and previously reported. The bill was referred to Committee on Veterans' Affairs.

Treaties and Executive Agreements

Congressman Bow (R., Ohio) in H. J. 327 proposed an amendment to the Constitution invalidating any provision of any treaty or executive agreement that denies or abridges the rights guaranteed by the Constitution. Treaties would become effective as internal law within the United States "only through legislation which would be valid in the absence of treaty." This bill, identical with S. J. Res. 1, the Bricker Amendment, and several other measures previously reported, was referred to the Judiciary Committee.

STATE MEDICAL LEGISLATION

Arizona

Bills Introduced.—H. 18, proposes the enactment of a licensing law for registered optometrists. H. 47, proposes the enactment of a premarital examination law that would require each party to a marriage to present a certificate from a duly licensed physician showing freedom from syphilis in a communicable stage. H. 73, proposes an appropriation to the state department of health for the establishment of a statewide preventive mental health program.

Kentucky

Bill Introduced.—S. 24, proposes the creation of a state medical education board and the establishment of a program thereunder granting loans and scholarships to medical students contracting to practice for a certain length of time in Kentucky after they have received their medical license.

Massachusetts

Bills Introduced.—H. 48, to amend the law relating to medical examination of minors, proposes that a physical examination by a registered physician or surgeon acting under the authority of the department of public health on the person of a minor who voluntarily submits thereto shall not constitute an assault or an assault and battery on such minor. H. 52, proposes to authorize the department of public health to prescribe and establish rules and regulations to control the transportation, packaging, distribution, production, and disposal of radioactive materials that may affect the public health or the health of persons exposed to radioactivity or ionizing radiation. H. 141, proposes to direct the University of Massachusetts to immediately establish, as a part of the university, schools of medicine and dentistry, the medical school to achieve and maintain standards of medical education prescribed by the American Medical Association for a grade A medical school. H. 255, proposes the creation of a board of registration of sanitarians and defines the word "sanitarian" as a person with a broad basic education in the physical, biological, and social sciences, supplemented by specialization in the field of sanitary sciences and technology, who is qualified to carry out instructional and inspectional duties and enforce the laws in the field of environmental sanitation. H. 481, proposes the creation of a board of registration of chiropractors and defines chiropractic as the science of locating and removing by hand adjustment only, interference with the transmission or expression of nerve force in the human body, by the correction of misalignment of subluxations of the vertebral column. It excludes operative surgery, prescription or use of drugs or medicines, or the practice of obstetrics, except that the x-ray and analytical instruments may be used solely for the purposes of examinations. H. 510, proposes to require the creation and establishment of a school of medicine to be located in the city of Boston or its vicinity to be under the management and control of the board of trustees of the University of Massachusetts. The medical school shall establish and maintain standards of admission, scholarship, and teaching, which shall be in accordance with standards approved by the Council on Medical Education and Hospitals of the American Medical Association. H. 546, proposes the creation of a special commission for the purpose of making an investigation and study relative to the training of medical laboratory technologists. H. 605, to amend the medical practice act, proposes to authorize applicants who fail to pass the examination given by the board to be reexamined twice

within the next two years. H. 606, to amend the law relating to physical therapists, proposes to require all registered physical therapists to renew their licenses annually. H. 607, proposes to set forth certain minimum standards of behavior to be observed by all doctors and other researchers at all times during experimentation, tests, and trials on human beings. Among other things, the proposal requires the express voluntary consent of the human subject to undergo medical or surgical experimentation, requires that a subject shall be given a thorough beforehand explanation of the project and of his right to withdraw from the experiment at any time and requires that the subject must have the legal capacity to give consent and be so situated as to be able to exercise free power of choice without the intervention of any element of force, fraud, deceit, duress, overreaching, secrecy concerning any and all details known to the experimenting doctor or researcher, or other ulterior form of constraint or coercion. The experiment to be performed must promise a recognizable likelihood that it will result in good for humanity, unprocureable by other means or methods of study, it shall be designed and based upon the knowable facts of medical art and science as to support a reasonable anticipation of resultant benefit to human beings, it shall be so conducted as to avoid all unnecessary physical and mental suffering and injury, it shall not be initiated or conducted at any stage of which there is reason to believe that death or disabling injury will possibly or probably occur. The degree of risk to the human experimental subject shall never exceed that determined by the humanitarian importance of the problem being studied. H. 608, proposes that no agency of the commonwealth or political subdivision thereof shall treat any public water supply with fluorine or any fluorine compound or make any water so treated available for general use in any hospital, school, or other institution, or transport, store, or hold in possession for such general use any fluorine or fluorine compound in any area contributory or contiguous to any public water supply. H. 641, proposes to direct the trustees of the University of Massachusetts to establish and maintain in metropolitan Boston a graduate school for instruction in the basic medical sciences, such school to achieve and maintain the standards of medical education prescribed by the American Medical Association for Grade A medical schools. H. 694, proposes to amend the law relating to reports of physicians and hospitals by providing that a physician or hospital officer who treats or visits a person addicted to the use of narcotics shall furnish forthwith to the department of public health the name and address of such person. H. 794 and H. 795, propose the enactment of a cash sickness compensation law. H. 945, proposes the creation of a Massachusetts memorial medical scholarship board to provide annual scholarships for the study of medicine and for the study of nursing. H. 1001, proposes the enactment of a disability benefits law. H. 1068, proposes the creation of a board of registration of dispensing opticians for the registration, examining, and licensing of persons desiring to practice as dispensing opticians. H. 1070, proposes to authorize the department of public health to establish and maintain an alcohol clinic in the city of Lawrence. H. 1184, proposes to direct the University of Massachusetts to immediately establish a school of medicine in the commonwealth. H. 1236, proposes the creation of a cash sickness compensation law. H. 1410, proposes to direct the trustees of the University of Massachusetts to construct and maintain a medical school affiliated with the University of Massachusetts to be located in or near Boston. H. 1423, proposes the establishment of a medical school by the trustees of the University of Massachusetts to be located in Boston or its vicinity. H. 1471, proposes the enactment of a sickness security act. H. 1489, proposes that whoever purchases or acquires a dog, cat, or bird to be used for experimentation of mutilation while alive shall keep a record and submit a report thereof to the commissioner of public safety and that such record shall be open to the inspection of the commissioner of public safety and all police officials. H. 1542, proposes that no person may be employed as a counselor or instructor in any recreational camp by any individual or organization unless such person has first undergone an examination by a qualified psychiatrist. H. 1766, to amend the medical practice act, proposes to require each physician to register his license annually. H. 1999, proposes the creation of a board of registration of chiropractors and defines chiropractic as the science of locating and adjusting by hand or by other means that may be recommended by chiropractic authority to increase efficiency, interference with transmission or expression of mental impulses (nerve forces) in the human body by correction of subluxations or misalignment of the vertebral column. X-ray and analytical instruments may be used for purposes of examination. It excludes the use of surgery. H. 2103, proposes to direct the trustees of the University of Massachusetts to establish and maintain one or more graduate schools for instruction in the basic medical sciences to be known as the University of Massachusetts Medical School, such school to achieve and maintain standards of medical education prescribed by the American Medical Association. H. 2138, proposes the enactment of a law establishing a system of compulsory nonindustrial accident and health insurance benefits. H. 2185, proposes that no person shall hold himself forth as a doctor unless he has received the degree of doctor in his field from a university, college, or school empowered to grant such degree and that all persons who wish to designate themselves as doctors shall affix immediately following their names the proper letters of academic usage pertinent to the degree which they hold. H. 2187, proposes that any hospital owned or operated by the commonwealth that gives treatment to patients afflicted with cerebral palsy shall procure sufficient facilities and provide adequate personnel to give such patients proper physical therapy treatment or such other treatment as it is deemed essential for their care. S. 20, to amend the law relating to the examination of school children, proposes that such children shall be separately and carefully tested and examined at least once each year in every school to ascertain defects in sight or hearing. S. 242, proposes the establishment in the department of education of a school of chiropody attached to the University of Massachusetts for the training of students in the field of foot care. S. 353, proposes the enactment of a cash sickness compensation act.

S. 457, to amend the law relating to physical therapy, proposes to define a registered physical therapist as a person registered under the act for the treatment of any bodily or mental condition of any person by the use of the physical, chemical, and other properties of heat, light, water, electricity, massage, and active and passive exercise.

Bill Enacted.—S. 243, has become Res. Ch. 1 of the Resolves of 1954. It provides for the continuance of a special commission established in 1951 to investigate the establishment of a state medical and dental school under the jurisdiction of the University of Massachusetts. This commission shall also consider, investigate, and study the establishment of a New England board of education, proposed compacts among the New England states authorizing cooperative planning in the field of medicine, dentistry, veterinary medicine, and technical, professional graduate training.

MEDICAL SOCIETY OF VIRGINIA

Seventeen physicians of Richmond and Manchester met on Dec. 15, 1820, to form the Medical Society of Virginia and the following month adopted a constitution. The preamble stated: "Considering that the science of medicine occupies a distinguished rank in the circle of the liberal arts and sciences, and that its advancement is intimately connected with the

happiness and prosperity of every well-regulated society: that the good people of this commonwealth have heretofore suffered great inconvenience and injury from an almost exclusive dependence on foreign institutions for instruction in the principles of this essential branch of knowledge: that the character and best interests of the state require that the evils of such dependence should, as far as possible, be removed, by the introduction of institutions of our own: and that an association having in view this object, long so highly prized and so anxiously expected by its liberal minded inhabitants, is now deemed practicable: a number of the members of the medical profession have formed themselves into a society. . . ." At the same session a resolution was adopted that provided "that no person holding in part or whole any patent medicines, or remedies for diseases, shall be eligible to a seat in this society; and any member who may hereafter become interested directly or indirectly, in any such patent, shall thereby absolutely forfeit his seat, and the word 'expelled' written opposite his name in the record book." Three years later, on Jan. 2, 1824, the society was incorporated—a rather futile gesture, since in November of that year its last meeting was held. Its demise was later attributed to "apathy and indifference which most unaccountably palsied the exertions of the profession." After 17 years the society, on Dec. 27, 1841, readopted the old constitution and began again.

Although its title implied statewide participation and despite the fact that some attempts at reorganization were made, for almost 10 years the society remained virtually a local Richmond organization, with some associate and nonresident members. Agitation against the control of the Richmond group was strengthened by the *Stethoscope*, the first Virginia medical journal, which focused attention on the need for a strong, unified front in working for medical legislation and called for repeal of the law that "taxed the profession of medicine, without protecting or even recognizing it, the enactment of laws for the suppressions of quackery, and the promotion of science, a registration act, a licentiate board, a proper coroner's system, and other measures of this character." A plan of reorganization was adopted in April, 1851. On April 27, 1852, the first annual meeting of the reorganized society was called. Resolutions were adopted favoring appointment by law of a board of medical examiners, elevation of standards of medical education, and support of those medical schools that would cooperate in carrying out the society's proposals for reform. As time went on, however, arguments over these matters grew to such proportions that little of the society's meeting time was devoted to scientific discussions, their place being usurped by attacks and counterattacks on medical teaching in Richmond, disputes over establishment of a society-owned journal, and even opposition to a previously adopted resolution that had requested a legislative bill "requiring that the venders of all secret nostrums be required to put on each package of their medicines a printed label, in plain English, stating the ingredients of which it is composed." Interest flagged, and at the annual meeting in Richmond in 1855, out of a membership of 450, only 20 persons (6 from outside the city) attended. In 1859 the society held its last meeting, its death being caused, as Dr. Wyndham B. Blanton points out, "not by the approaching war but by insistence upon a resolution advocating a board of medical examiners."

Eleven years later, at the call of the medical societies of Abingdon, Lynchburg, and Richmond, a convention of 147 physicians met at the Medical College of Virginia in Richmond to organize again the Medical Society of Virginia, the present society, which was incorporated Jan. 14, 1871. The group urged "our medical brethren in the several towns and cities of Virginia to convene and organize local societies auxiliary to the Medical Society of Virginia" and opposed "the low-fee and eleemosynary system of education at present in vogue in some of the medical schools of the country."

Over the years the society fought for various legislative measures. An approximately 30-year war for a board of medical examiners, culminated in passage of the acts of 1883-1884. Dr. Blanton discusses the acts in the trilogy "Medicine in Virginia," which, prepared under the direction of the Medical Society of Virginia, deals with the state's medical history from 1607 to 1900.

In the current century, membership in the society has risen to 2,368 in 46 component societies. Its headquarters at 1105 W. Franklin St., Richmond, accommodate not only its own offices but those of the Virginia Academy of General Practice and the *Virginia Medical Monthly*, the society's official publication. Established in April, 1874, as the *Virginia Medical Monthly*, its name was changed to the *Virginia Medical Semi-Monthly* in April, 1896, but reverted to its first and present title in January, 1918, when it was purchased by the society.

On Jan. 5 a conference on problems of the medically indigent, sponsored in Richmond by the society and the Virginia Council on Health and Medical Care, was attended by officers of component medical societies, members of the county boards of supervisors, state civic groups, the Virginia Hospital Association, and members of the state legislature. On Nov. 1-3 the society will join with the Medical Society of the District of Columbia in "The First Interstate Scientific Assembly of the Medical Society of the District of Columbia and the Medical Society of Virginia." The annual meeting of the society will be held in Roanoke, Oct. 18-21. Its officers are Dr. Vincent W. Archer, Charlottesville, president; Dr. Carrington Williams, Richmond, president-elect; Drs. David S. Garner, Frank E. Tappan, and A. Tyree Finch, Farmville, vice-presidents; and Robert I. Howard, Richmond, executive secretary-treasurer.

MEDICAL NEWS

DISTRICT OF COLUMBIA

Seminar on Hepatic Disease.—"Diseases of the Liver and Biliary Tract," the third Midwinter Seminar of the Medical Society of the District of Columbia, will be held Feb. 16-18 at 8 p. m. in the medical society building, 1718 M St., N. W., Washington, D. C. The guest moderator will be Dr. Franklin M. Hanger, professor of medicine, Columbia University College of Physicians and Surgeons, New York. The Tuesday evening program on jaundice will include discussions on bile formation, infectious hepatitis, differential diagnosis of jaundice, and the presentation of case problems. Case problems will also be presented at the Wednesday program on portal hypertension, which will include the following papers:

- Portal Circulation; Mechanisms of Ascites, Major Edward J. Jahnke Jr., Washington, D. C.
- Hematemesis in Portal Cirrhosis, Lt. Col. Eddy D. Palmer, Washington, D. C.
- Differential Diagnosis in Ascites, Franklin M. Hanger, New York.

On Thursday evening the following symposium on therapy will be presented:

- Outline of Therapy in Diseases of the Liver and Biliary System, Franklin M. Hanger, New York.
- Medical Therapy in Hepatic Disease, Gerald B. Phillips, Bethesda, Md.
- Medical Therapy in Biliary Tract Disease, Thomas S. Sappington, Washington, D. C.
- Treatment of Hemolytic Jaundice, Charles E. Rath, Washington, D. C.
- Indications for Gallbladder Surgery, William S. McCune, Washington, D. C.
- Indications for Portacaval and Other Shunts, Charles A. Hufnagel, Washington, D. C.

Society News.—The District of Columbia Society for Crippled Children is sponsoring lectures at the society headquarters, 1767 Massachusetts Ave., N. W. On Feb. 16, 3:30-4:30 p. m., "Intrauterine and Neonatal Infections and Brain Damage" will be presented by Dr. Mario Mollari, professor of bacteriology, Georgetown University School of Medicine, Washington, D. C. On Feb. 23 Dr. Morris I. Michael, instructor of medicine, Georgetown University School of Medicine, will discuss "Metabolic Disturbances and Brain Damage."

ILLINOIS

Appointments by the Governor.—Gov. William G. Stratton has named the following physicians to serve in public health agencies: Drs. Theodore R. Van Dellen, Chicago, and Harlan A. English, Danville (Hospital Licensing Board); Drs. Fred H. Decker, Peoria, Gilbert H. Edwards, Pinckneyville, and James P. Grier, Evanston (Advisory Board to the Bureau of Cancer Control); and Dr. Irving H. Neece, Decatur (Advisory Hospital Council).

Narcotic Violation.—Dr. George G. Moore, 209 W. Fifth St., Benton, pleaded guilty in the U. S. District Court at Benton to a violation of the federal narcotic law. On Nov. 19, 1953, sentence was suspended, and he was placed on probation for three years and was fined \$750.

Chicago

Robins Memorial Meeting.—The Chicago Medical Society and the Chicago Pediatric Society will assemble for a joint session, Feb. 16, 8 p. m., at the Nurses' Home, Children's Memorial Hospital, 707 Fullerton Ave., for the Dr. Louis S. Robins memorial meeting. Dr. Sidney O. Levinson has been invited to present "His Early Years" and Drs. William Saphir and Otto Saphir, "His Illness." "Myasthenia Gravis" will be discussed by the guest speaker, Dr. Lee McKendree Eaton, professor of neuropsychiatry, Mayo Foundation, Rochester, Minn. Telephone messages may be received at Diversey 8-4040.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Society News.—The Chicago Diabetes Association and Service Unit announces the opening of its new office, Room 909, Mallers Bldg., 5 S. Wabash Ave., Chicago 3; telephone ANdover 3-1861. Visitors are welcome Monday through Friday from 10:30 a. m. to 3:30 p. m. —The Institute of Medicine of Chicago announces the election of the following officers for 1954: president, Dr. Willis J. Potts; vice-president, Dr. Don C. Sutton; secretary, Dr. George H. Coleman; and treasurer, Dr. E. Lee Strohl. —On Feb. 18, 8 p. m., the Jackson Park branch of the Chicago Medical Society in cooperation with the Chicago Heart Association will present "The Use of Anticoagulant Drugs" by Dr. Emmet B. Bay, University of Chicago School of Medicine. Discussions on the program, which will be held at Billings Memorial Hospital, 950 E. 59th St., are Dr. Norman B. Roberg of the University of Illinois College of Medicine and Dr. George F. O'Brien of the Stritch School of Medicine of Loyola University. Reservations for the dinner, 7 p. m., must be made by noon, Feb. 18, through Dr. Andrew J. Brislen (Midway 3-0400). —At 9:30 p. m., Feb. 18, the West Side branch of the Chicago Medical Society in cooperation with the Chicago Heart Association will hold a round-table conference on acute coronary disease at St. Anne's Hospital, 4950 W. Thomas St. (EStebrook 8-7100). "Pathological Aspects" will be presented by Dr. William B. Wartman, "Diagnosis" by Dr. Gilbert H. Marquardt, and "Treatment" by Dr. Lyle A. Baker, who will also serve as moderator. The panel members are all from Northwestern University Medical School. All physicians are invited to both of these meetings.

INDIANA

Medical Civic Dinner.—The Vanderburgh County Medical Society announces that Frederick C. Othman, Washington, D. C., Scripps-Howard newspaper columnist, will present "Confusion on the Potomac" at the annual Medical Civic Dinner, Hotel McCurdy, Evansville, Feb. 18.

MARYLAND

Society News.—Dr. Kenneth K. Keown, associate professor of anesthesiology, Hahnemann Medical College and Hospital of Philadelphia, will present an illustrated lecture on hypothermia at the meeting of the Baltimore City Medical Society, Feb. 19, 8:30 p. m., in Osler Hall, 1211 Cathedral St.

Lecture on Carcinoma of the Cervix.—Dr. Isadore Lampe, professor of roentgenology, University of Michigan Medical School, Ann Arbor, will discuss "Radiation Therapy of Carcinoma of the Cervix" at a joint meeting of the Radiological Section of the Medical and Chirurgical Faculty of the State of Maryland and the Obstetrical and Gynecological Society of Maryland, Feb. 16 at the Sheraton Belvedere Hotel, Baltimore. A roentgenogram reading session, 5:30 p. m., will precede dinner, which will be followed by the scientific session at 8:30. All who are interested are invited to attend the film reading session and the formal lecture.

MASSACHUSETTS

House Officers Sponsor Lecture.—The House Officers' Association, New England Center Hospital, Boston, announces that on Feb. 19 at 7 p. m. Dr. Thomas P. Almy, New York, will discuss "Experimental Evidence on the Nature of Cardiospasm" in the Stearns Auditorium of New England Center Hospital. All interested persons are invited.

Radioactive Isotopes.—The annual Tufts Medical Alumni lecture will be given at the Tufts College Medical School, Boston, Feb. 16, 11 a. m. Dr. Patrick J. Fitzgerald, professor of pathology, State University of New York College of Medicine at New York City, Brooklyn, will discuss "Radioactive Isotopes in Pathology." Physicians and students are invited.

NEBRASKA

Nebraska Hospitals Built with Hill-Burton Aid.—The Nebraska State Department of Health in cooperation with the Nebraska State Medical Society, the Nebraska Hospital Association, and the University of Nebraska made a state-wide survey in 1945 of its acceptable beds in general hospitals. This survey formed a basis for the initial state plan developed under the Hospital Construction and Survey Act (Hill-Burton program), which was approved by the U. S. Public Health Service in January, 1948. Then in 1953 after a period of intensive construction work, the state department of health completed another hospital survey

The total cost of all general hospital and allied construction completed or under contract as of January, 1954 is estimated to be 18 million dollars, and of this the Nebraska State Agency has allocated federal funds in excess of \$5,300,000. The estimated cost of similar projects definitely programed, but not yet under contract, is in excess of 11 million dollars, and of this about 5 million dollars in contracts will be let during the current year. The estimated cost of projects now developing at the local level and having a reasonable chance of success is 2 million dollars. Some of the hospitals aided by the Hill-Burton program are shown on the opposite page.

trade area population of about 5,000. It has a maximum capacity of 30 adults together with 10 bassinets. The construction costs were \$275,000, the equipment \$45,000, and the architect's fees and miscellaneous costs \$17,000. The Community Memorial Hospital at Ogallala in Keith County, also constructed under the Hill-Burton program, received its first patient in September, 1952. The total service area population of this community is between 5,000 and 6,000. The hospital has a capacity for 30 adults and 10 bassinets. All patient rooms have semiprivate or private accommodations. The construction costs of this hospital were \$367,000, the equipment \$52,000 and the architect's fees and miscellaneous costs \$22,000. The Kearney County Community Hospital at Minden, which is expected to be completed in April, 1954, will provide accommodations for 25 adults and 8 newborn infants. The service area population of this community is about 4,500. The patient

Reading from top and left to right are the Nebraska Psychiatric Institute, Omaha; Immanuel School of Nursing, Omaha; County Community Hospital, Minden; Community Memorial Hospital, Ogallala; Memorial Hospital, Schuyler.

accommodations are semiprivate in design, and all rooms have toilet and lavatory. The construction costs are estimated to be \$290,000, the equipment \$40,500, and the architect's fees and miscellaneous costs \$17,500. The Immanuel Deaconess Institute of Nursing at Omaha is being constructed under the Hill-Burton program and is expected to be completed in September, 1954. This major addition will more than double the capacity of the present school of nursing and provide accommodations for 100 students, class rooms, and an auditorium. The estimated construction costs are \$458,000, the equipment costs \$65,000, and the architect's fees and miscellaneous costs \$28,000.

The Hospital Survey and Construction Act (Hill-Burton program) provided funds approximating 30% of the total costs of such projects completed on July 1, 1953. While federal funds have supported only part of hospital construction in Nebraska during this period, the Hill-Burton program has stimulated hospital construction undertaken with local resources.

NEW YORK

Dr. Ravdin to Deliver Roswell Park Lecture.—On Feb. 18 the Buffalo Surgical Society will sponsor the Roswell Park lecture by Dr. Isidor S. Ravdin, professor of surgery, University of Pennsylvania School of Medicine, Philadelphia. Dr. Ravdin will be awarded the society's gold medal given in honor of Dr. Roswell Park, professor of surgery, University of Buffalo, 1883-1914.

Society News.—A course on resuscitation of the newborn will be given for residents and interns under the auspices of the Child Health and Welfare Committee of the Medical Society of the County of Kings Feb. 15, 1 p. m., in the auditorium of the "E" Building, Kings County Hospital, Clarkson and New York Avenues, Brooklyn. Members of the profession are

invited to hear Drs. Peter Gruenwald, assistant professor, obstetrics and gynecology (pathology), Richard L. Day, professor of pediatrics, and Merel H. Harmel, professor and executive officer, department of anesthesiology, State University of New York College of Medicine at New York City, Brooklyn.—"Heart Disease and Pregnancy" will be discussed at the meeting of the Medical Society of the County of Kings in McNaughton Auditorium, Brooklyn, Feb. 16. "Immediate and Remote Prognosis" will be presented by Leon C. Chesley, Ph.D., associate professor, State University of New York College of Medicine at New York City, Brooklyn. Dr. Charles A. Gordon, Brooklyn, chairman, Committee on Maternal Welfare, will have as his topic "Brooklyn 1937-1952," and the summary will be given by Dr. Louis M. Hellman, Brooklyn.

New York City

Tumor Clinic.—Dr. George T. Pack will discuss "Tumors of the Liver" at the Tumor Clinic Conference at Harlem Hospital Feb. 17 at 10:45 a. m.

Harvey Lecture.—Britton Chance, Ph.D., professor of medical physics, the Eldridge Reeve Johnson Foundation for Medical Physics, University of Pennsylvania, Philadelphia, will deliver the sixth Harvey lecture of the 1953-1954 series at the New York Academy of Medicine, Feb. 18. He will discuss "Enzymes in Action in Living Cells."

Dermatologic Lecture.—Dr. Nathan Sobel, associate professor of clinical dermatology and syphilology, Post-Graduate Medical School of the New York University-Bellevue Medical Center, will lecture on "Skin Diseases with Accompanying Oral Mucous Membrane Lesions" at the monthly conference of the New York Institute of Clinical Oral Pathology at the New York Academy of Medicine, Feb. 15, 8:30 p. m.

Gifts to University.—New York University announces receipt of a gift of \$1,268,941 from the Samuel H. Kress Foundation toward the construction of the \$8,500,000 medical science building scheduled for completion next spring at the New York University-Bellevue Medical Center. The new gift from the Kress Foundation brings to \$3,882,000 the amount it has contributed to the center, about half for current support of the Post-Graduate Medical School of the New York University-Bellevue Medical Center and half for capital purposes in the construction of new facilities. The new building, a key structure in the \$29,500,000 medical center, will provide facilities for the Post-Graduate School of Medicine and the College of Medicine, research laboratories, offices, library, and student facilities. The university also announced receipt of \$105,000 from Mr. Winthrop Rockefeller, Little Rock, Ark., former chairman of the board of trustees of New York University-Bellevue Medical Center, who was recently elected a permanent honorary trustee in recognition of the time and service which, for many years, he has devoted toward the growth and development of the center. University Hospital will receive \$26,250 of the gift for medical, surgical, dietary, and housekeeping equipment. The balance will be applied toward construction costs of the medical science building.

OHIO

Special Train to San Francisco.—The Ohio State Medical Association has arranged for a special train to the American Medical Association annual meeting in San Francisco, June 21-25. The all-room, air-conditioned train will leave Chicago June 12, reaching San Francisco June 20. Entertainment and tours have been arranged for stopovers in Salt Lake City (about 1 day), Los Angeles (2 days), and Yosemite National Park (2 days). On the return trip stops will be made at Portland, Ore.; three days and nights will be spent at Glacier National Park; and the party will arrive in Chicago July 3. The cost of the trip (about \$500 per person) includes all traveling expenses except meals and sightseeing at Los Angeles and San Francisco, one meal in Portland, and round-trip rail and Pullman fare between home city and Chicago. A booklet concerning the trip, will be mailed, on request to Mr. C. S. Nelson, secretary, 79 E. State St., Columbus 15.

OKLAHOMA

MacKenzie Memorial.—Dr. William J. Bryan Jr., Tulsa, has announced plans to have an oil portrait of the late Dr. Ian MacKenzie painted and hung at Hillcrest Medical Center as a permanent memorial. Contributions may be sent to the Tulsa County Medical Society offices, B-9 Medical Arts Building, Tulsa. Checks should be made payable to Mary Russell, treasurer.

General Practitioners Meet in Tulsa.—The annual meeting of the Oklahoma Academy of General Practice will be held Feb. 15-16 at the Tulsa Hotel in Tulsa. Out-of-state speakers and their first presentations include:

- William F. Guerriero, Dallas, Texas, Carcinoma of the Cervix.
- Horace L. Hodes, New York, Treatment of the Severe Forms of Polymyositis, and the Present Status of Measures Aimed at the Prevention of the Disease.
- Manuel E. Lichtenstein, Chicago, Clinical Significance of the Position and Station of the Appendix.
- Perrin H. Long, Brooklyn, Uses and Abuses of the Antibiotics.
- Carlo S. Scuderi, Chicago, Backache, from the Standpoint of a General Practitioner—Diagnosis and Treatment.

PENNSYLVANIA

University News.—The University of Pennsylvania announces establishment in the School of Veterinary Medicine of a department of preventive medicine and hygiene, primarily for the conduct of research on infectious diseases of animals, and to intensify research into animal diseases that may be communicated to man. Headquarters from which the department will function will be based on New Bolton Center, the university's 225-acre center in Chester county, near Kennett Square. The University is completing a laboratory building that will house the new department. Raymond Fagan, D.V.M., senior scientist in the communicable disease center of the U. S. Public Health Service, Kansas City, Kan., has been appointed chairman of the department, with the faculty status of associate professor of preventive medicine and hygiene in the veterinary school. In his most recent work at Kansas City Field Station Communicable Disease Center, Dr. Fagan has been stressing the epidemiology of animal-born diseases, such as rabies, leptospirosis, brucellosis, and psittacosis. He is an associate editor of the *Journal of the American Veterinary Medical Association*.

Philadelphia

Forum on Rehabilitation.—The Philadelphia County Medical Society, Health and Welfare Council, and the Hospital Council of Philadelphia will sponsor the forum "Rehabilitation and Medical Practice" at the Medical Society Auditorium, Feb. 18, 4-5:30 p. m.

Personal.—Dr. Robert D. Dripps, professor of anesthesiology in surgery, University of Pennsylvania School of Medicine, has been appointed senior civilian consultant in anesthesia to the Surgeon General of the Army. —Dr. William S. Blakemore, an associate in surgery in the University of Pennsylvania School of Medicine, left Philadelphia in September for Stockholm, Sweden, to spend a year in special investigative work on surgery of the heart and lungs. Dr. Blakemore also is the beneficiary this year of the I. S. Ravdin Traveling Fellowship, which was awarded him on the basis of skill in surgical practice and research. —Dr. Daniel J. McCarthy, one of the founders of the National Tuberculosis Association and one of the four remaining original staff members of the Henry Phipps Institute in Philadelphia, has been given the Distinguished Service Cross by the Palm Beach County (Fla.) Tuberculosis and Health Association in recognition of his 50 years of service to the voluntary tuberculosis movement. From 1903 to 1906 Dr. McCarthy was a director of the Pennsylvania Society for the Prevention of Tuberculosis, now the Pennsylvania Tuberculosis and Health Society.

TEXAS

Obstetricians and Gynecologists Meet in Waco.—The Texas Association of Obstetricians and Gynecologists will hold its annual meeting in Waco Feb. 19-20 at the Roosevelt Hotel. Practicing physicians are invited. Dr. Carl T. Javert, associate professor of obstetrics and gynecology, Cornell University Medical College, New York, will speak on (1) the pathology of spontaneous abortions and (2) pelvic lymphatics and gynecologic disease. The annual banquet will be on Friday.

Muscular Dystrophy Grant.—The National Muscular Dystrophy Research Foundation has made a grant of \$5,000 to the Southwest Foundation for Research and Education in San Antonio, for use in a project, entitled "Individual Metabolic Patterns for Families Having a History of Muscular Dystrophy." The foundation is cooperating in the selection of families who are subjects of the studies. Progressive changes in the individual metabolism of each subject will be compared both within and between families for a three year period. Those wishing to make application for moderate grants-in-aid should apply to the Executive Secretaries, National Muscular Dystrophy Research Foundation, Inc., 709 Main St., Liberty. Dr. Albert L. Delaney, Liberty, is president of the foundation, and Dr. Derek E. Denny-Brown, Harvard Medical School, Boston, is chairman of the foundation's research advisory board, which made the grant.

GENERAL

Catastrophic Fatalities.—According to the Metropolitan Life Insurance Company, catastrophes (accidents killing five or more persons) took about 1,800 lives in the United States in 1953, the highest annual toll since 1947. A major factor in the rise was the unusually heavy loss of life in tornadoes, 13 tornadoes (4 in well populated areas) having killed more than 450 persons. Other tragedies, each claiming more than 25 lives, included aircraft crashes (5 with a total of 193 deaths) and explosions/fires (3 with a total of 105 victims).

American Journal of Gastroenterology.—The National Gastroenterological Association announces that the name of its official publication, established in 1934, has been changed from *The Review of Gastroenterology* to *The American Journal of Gastroenterology*, effective with the January, 1954, issue. The publication will continue to be edited by Dr. Samuel Weiss and a board consisting of Drs. Milton J. Matzner, Brooklyn, James T. Nix, New Orleans, and Michael W. Shutkin, Milwaukee. The association and the journal also announce the removal of their offices from 1819 Broadway to 33 W. 60th St., New York 23 (phone: Circle 6-4345).

Examinations for Orthoptic Technicians.—The annual examination of orthoptic technicians by the American Orthoptic Council will be conducted in July and September. The written examination, nonassembled, will take place July 22 in certain assigned cities and offices. The oral and practical examinations will be on Sept. 18 in New York, preceding the meeting of the American Academy of Ophthalmology and Otolaryngology. Application for examination must be received before June 1 by the office of the Secretary of the American Orthoptic Council, Dr. Frank D. Costenbader, 1605 22nd St. N.W., Washington 8, D. C. and must be accompanied by the examination fee of \$30.

Prizes for Dissertations on Epilepsy.—The American League Against Epilepsy announces the Jerry Price memorial prizes, totaling \$1,000, contributed jointly by Mr. and Mrs. Fred Markham and the league: first prize, \$500; second prize, \$200; and third prize, \$100; with book prizes for other contestants and possible publication of one or more contributions in the journal *Epilepsia*. The contest is open to the students of any approved medical school in the United States or Canada. Any one of the many aspects of epilepsy may be covered. Essays should be original, typed double-spaced, and preferably not more than 5,000 words. Contributions should be mailed before Aug. 1, to Dr. Jerome K. Merlis, Secretary, American League Against Epilepsy, 150 S. Huntington Ave., Boston 30.

Teaching Home Nursing Via TV.—Tests to determine the effectiveness of television for teaching home nursing are being carried out in Houston, Texas, and Oklahoma City during February and March. Three groups of 200 women each will be used in the test: 1. Students in Oklahoma City will form the control group, taking the standard home nursing course in classrooms only. 2. In Houston, one group will receive all instruction via television over the University of Houston educational TV station KUHT. 3. A second group will watch the TV lesson once a week and then receive supplemental instruction in neighborhood meetings. The three groups will be tested before and after the course, and results will be evaluated to determine the relative effectiveness of the three methods of instruction. The American Council on Education has made a grant to pay for kinescoping the programs.

Fellowships in Biometry and Epidemiology.—The American Cancer Society has established at the Yale University Graduate School of Medicine, New Haven, predoctoral and postdoctoral fellowships in biometry and epidemiology to promote the knowledge of statistical methods. Candidates who express intention of following a career in a discipline applicable to (1) the study of growth, typical or malignant, (2) the study of the epidemiology of cancer and other chronic diseases, or (3) clinical research in cancer will be favored. Fellows will be expected to carry out research in one of these fields. Applicants

for predoctoral fellowships must have the degree of bachelor of arts or bachelor of science and a knowledge of biology, chemistry, mathematics, and physics. They are expected to enter the graduate school as candidates for the doctor of philosophy degree, and they will be given training in one or more fields of biology, as well as statistics. The fellowships, awarded for three years, may be terminated at any time if the candidate fails to meet the standards of the university. Annual stipends will be \$2,000. Additional funds may be available for students with dependents.

The postdoctoral fellowships are intended for young men and women embarking on an investigative career and also for more mature investigators desiring to extend their fields of competence. Candidates must be citizens of the United States who possess the degree of doctor of medicine, doctor of philosophy, or doctor of science. Fellowships, awarded for periods of one year, may be renewed for two additional years. The stipends will range from \$3,000 to \$4,500, depending on individual circumstances. For information, write to Prof. E. Cuyler Hammond, Director of Graduate Studies in Biometry, 51 Hillhouse Ave., Yale University, New Haven. Application blanks for predoctoral fellowships may be obtained from the Dean of the Graduate School, Yale University, New Haven. All applications for both types of fellowships should be mailed by Feb. 28.

Society News.—Newly elected officers of the Western Surgical Association include: Dr. Herbert H. Davis, Omaha, president; Dr. Michael L. Mason, Chicago, secretary; and Dr. Howard E. Snyder, Winfield, Kan., treasurer. —Officers of the American Society of Ophthalmologic and Otolaryngologic Allergy include Dr. Albert D. Ruedemann, Detroit, president; Dr. F. Lambert McGannon, Lakewood, Ohio, president-elect; and Dr. Michael H. Barone, Buffalo, secretary-treasurer. —At the annual meeting of the board of commissioners of the Joint Commission on Accreditation of Hospitals, officers elected included: Dr. Newell W. Philpott, Montreal, Canada, chairman; Dr. LeRoy H. Sloan, Chicago, vice-chairman; Stuart K. Hummel, Milwaukee, treasurer; and Dr. Edwin L. Crosby, Chicago, secretary. —Dr. Henry R. Viets, Boston, was reelected to the chairmanship of the medical board of the Myasthenia Gravis Foundation, Inc. at its recent annual meeting. Dr. George D. Gammon, Philadelphia, was elected vice-chairman, and Dr. Robert S. Schwab, Boston, secretary. —At the annual meeting of the American Roentgen Ray Society in Cincinnati, the following officers were elected: president-elect, Dr. Joshua C. Dickinson, Tampa, Fla.; secretary, Dr. Barton R. Young, Philadelphia, (reelected); and treasurer, Dr. Wendell G. Scott, St. Louis, (reelected). The president is Dr. Harry M. Weber, Rochester, Minn. —At its annual meeting in Louisville, the American Academy of Tropical Medicine elected the following officers: president, Brig. Gen. George R. Callender, U. S. Army, retired, Washington, D. C.; vice-president, Capt. James J. Saper, U. S. N., Washington, D. C.; secretary, Dr. E. Harold Hinman, San Juan, Puerto Rico; treasurer, Justin M. Andrews, Sc.D., Washington, D. C.; and councillor (for a five year term), Quentin M. Geiman, Ph.D., Boston. —The American Federation for Clinical Research announces that Feb. 15 is the abstract deadline for papers to be presented at the national meeting, Atlantic City, N. J., May 2. Abstracts, not exceeding 250 words and postmarked not later than Feb. 15, should be submitted in triplicate to the national secretary, Dr. Lawrence E. Hinkle Jr., 525 E. 68th St., Room F-611, New York.

LATIN AMERICA

Congress of Otorhinolaryngology and Bronchoesophagology.—The fourth Pan American Congress of Otorhinolaryngology and Bronchoesophagology will be held in Mexico, D. F., from Feb. 28 to March 4 under the sponsorship of the government of the republic of Mexico and the Mexican Society of Otorhinolaryngology and Bronchoesophagology. Round tables have been scheduled on tumors of the esophagus, teaching of otorhinolaryngology and bronchoesophagology, and evaluation of the hypoacusias. Topics for discussion include endocranial tumors, vertiginous syndromes, occupational deafness, nasal allergy, bilateral paralysis of the larynx, bronchial tumors, and esophageal varices.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

ANNUAL CONGRESS ON INDUSTRIAL HEALTH, Brown Hotel, Louisville, Ky., Feb. 24-25. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago 10, Secretary.

NATIONAL CONFERENCE ON RURAL HEALTH, Baker Hotel, Dallas, Texas, Mar. 4-6. Mrs. Arline Hibbard, 535 N. Dearborn St., Chicago 10, Secretary.

AERO MEDICAL ASSOCIATION, Hotel Statler, Washington, D. C., March 29-31. Dr. Thomas H. Sutherland, P. O. Box 26, Marion, Ohio, Secretary.

AMERICAN ACADEMY OF FORENSIC SCIENCES, Drake Hotel, Chicago, Feb. 25-27. Prof. Ralph F. Turner, Michigan State College Dept. of Police Administration, East Lansing, Mich., Secretary.

AMERICAN ACADEMY OF GENERAL PRACTICE, Cleveland, March 22-25. Mr. Mac F. Cahal, 406 West 34th St., Kansas City 2, Mo., Executive Secretary.

AMERICAN ASSOCIATION OF ANATOMISTS, Hotel Galvez, Galveston, Texas, April 7-9. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

AMERICAN ASSOCIATION OF PATHOLOGISTS AND BACTERIOLOGISTS, Houston, Texas, April 8-10. Dr. Alan R. Moritz, 2085 Adelbert Road, Cleveland 6, Secretary.

AMERICAN ASSOCIATION OF RAILWAY SURGEONS, Drake Hotel, Chicago, April 6-8. Dr. Chester C. Guy, 5800 Stony Island Ave., Chicago 37, Secretary.

AMERICAN COLLEGE OF ALLERGISTS, Roney Plaza Hotel, Miami Beach, Fla., April 5-10. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

AMERICAN HEART ASSOCIATION, Conrad Hilton Hotel, Chicago, April 1-4. Dr. William H. Bunn, 44 East 23d St., New York 10, Secretary.

AMERICAN ORTHOPSYCHIATRIC ASSOCIATION, Hotel Commodore, New York, March 11-13. Dr. Marion F. Langer, Room 210, 303 Lexington Ave., New York 16, Executive Secretary.

AMERICAN PHYSIOLOGICAL SOCIETY, Ambassador Hotel, Atlantic City, N. J., April 10-16. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Executive Secretary.

AMERICAN PSYCHOSOMATIC SOCIETY, Jung Hotel, New Orleans, March 27-28. Dr. Theodore Lidz, 333 Cedar St., New Haven 11, Conn., Secretary.

AMERICAN RADIUM SOCIETY, The Homestead, Hot Springs, Va., March 14-16. Dr. Robert E. Fricke, 102 Second Ave. S.W., Rochester, Minn., Secretary.

CENTRAL SURGICAL ASSOCIATION, Statler Hotel, Detroit, Feb. 18-20. Dr. Robert M. Zollinger, University Hospital, Columbus 10, Ohio, Secretary.

CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE, Palmer House, Chicago, March 2-5. Dr. Maurice M. Hoeltgen, 86 East Randolph St., Chicago, Secretary.

DALLAS SOUTHERN CLINICAL SOCIETY, Dallas, March 15-18. Dr. T. Haynes Harvill, 433 Medical Arts Bldg., Dallas 1, Texas, Secretary.

EASTERN SECTION, AMERICAN CONGRESS OF PHYSICAL MEDICINE, Newark, N. J., April 10. Dr. H. L. Rudolph, 400 North Fifth St., Reading, Pa., Secretary.

EASTERN SURGICAL SOCIETY, Boston, March 26-27. Dr. J. William Hinton, 130 East 79th St., New York, Secretary.

ISTHMIAN CANAL ZONE, MEDICAL ASSOCIATION OF THE, El Panama Hotel, Panama City, R. P., March 24-26. Dr. I. Robert Berger, Box "A," Balboa Heights, Canal Zone.

MICHIGAN CLINICAL INSTITUTE, Sheraton-Cadillac Hotel, Detroit, March 10-12. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Mich., Secretary.

MISSOURI STATE MEDICAL ASSOCIATION, Hotel Jefferson, St. Louis, April 4-7. Dr. E. Royce Bohrer, 634 North Grand Blvd., St. Louis 3, Secretary.

NATIONAL CONFERENCE ON CARE OF THE LONG-TERM PATIENT, Edgewater Beach Hotel, Chicago, March 18-20. Dr. Dean W. Roberts, 615 N. Wolfe St., Baltimore 5, Director.

NATIONAL CONFERENCE ON TRICHINOSIS, A. M. A. Headquarters, Chicago, March 1. Dr. S. E. Gould, Wayne County General Hospital, Eloise, Mich., Chairman.

NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS, Jefferson Hotel, St. Louis, March 10-12. Dr. F. M. Foote, 1790 Broadway, New York 19, Executive Director.

PACIFIC NORTHWEST SOCIETY OF PLASTIC AND RECONSTRUCTIVE SURGEONS, Seattle, April 3. Dr. E. E. Banfield, Medical Arts Bldg., Tacoma 2, Wash., Secretary.

REGIONAL MEETINGS, AMERICAN COLLEGE OF PHYSICIANS:
TOPEKA, KANS., March 19. Dr. William C. Menninger, 3617 West 6th Ave., Topeka, Kansas, Governor.

RICHMOND, VA., Feb. 25. Dr. Charles M. Caravati, 807 West Franklin St., Richmond 20, Va., Governor.

SOUTHERN CALIFORNIA, Riverside, Feb. 13-14. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

SECTIONAL MEETINGS, AMERICAN COLLEGE OF SURGEONS:

FRENCH LICK SPRINGS, Indiana, French Lick Springs Hotel, March 15-17.

Dr. Carl H. McCaskey, 20 N. Meridian St., Indianapolis 4, Chairman.

MONTREAL, CANADA, Mount Royal Hotel, March 31-April 2. Dr. Harry S. Morton, 900 Sherbrooke St., West, Montreal, Canada, Chairman.

OMAHA, NEB., Hotel Fontenelle, March 1-4. Dr. Earl A. Connolly, 107 South 17th St., Omaha, Chairman.

RENO, NEV., Riverside Hotel, Feb. 25-26. Dr. Kenneth F. Maclean, 120 N. Virginia St., Reno, Nev., Chairman.

SOUTHEASTERN ALLERGY ASSOCIATION, Dinkler-Plaza Hotel, Atlanta, Ga., March 25-27. Dr. Katharine B. MacLinnis, 1515 Bull St., Columbia 1, S. C., Secretary.

SOUTHEASTERN SURGICAL CONGRESS, Tutwiler Hotel, Birmingham, Ala., March 8-11. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta, Ga., Secretary.

WESTERN SOCIETY OF ELECTRO-ENCEPHALOGRAPHY, Del Monte Lodge, Pebble Beach, Calif., March 7-8. Dr. Sylvester N. Berens, 902 Boren Ave., Seattle, Secretary.

FOREIGN AND INTERNATIONAL

ASSOCIATION OF SURGEONS OF GREAT BRITAIN AND IRELAND, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

BRITISH MEDICAL ASSOCIATION, Glasgow, Scotland, July 1-9, 1954. Dr. A. Macrae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

CANADIAN MEDICAL ASSOCIATION, Vancouver, B. C., Canada, June 14-18, 1954. Dr. T. C. Routley, 244 St. George St., Toronto 5, Ont., Canada, General Secretary.

CONFERENCE OF INTERNATIONAL UNION AGAINST TUBERCULOSIS, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

CONGRESS OF INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF BLINDNESS, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

CONGRESS OF INTERNATIONAL ASSOCIATION FOR THE STUDY OF THE BRONCHI, Geneva, Switzerland, June 5-6, 1954. Professor A. Montandon, Clinique Universitaire d O.R.L., Hôpital Cantonal, Geneva, Switzerland, Chairman.

EUROPEAN SOCIETY OF CARDIOVASCULAR SURGERY, Edinburgh, Scotland, July 9-10, 1954. For information address: Mr. A. J. Slessor, Department of Surgery, University New Building, Edinburgh 8, Scotland.

HEALTH CONGRESS OF THE ROYAL SANITARY INSTITUTE, Scarborough, England, April 27-30, 1954. Mr. P. Arthur Wells, Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1, England, Secretary.

INTERNATIONAL ANESTHESIA RESEARCH SOCIETY, Los Angeles, Calif., U. S. A., Oct. 10-14, 1954. For information write: Dr. T. H. Seldon, 102-110 Second Avenue S.W., Rochester, Minn., U. S. A.

INTERNATIONAL CANCER CONGRESS, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

INTERNATIONAL CONFERENCE ON THROMBOSIS AND EMBOLISM, Basle, Switzerland, July 20-24, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

INTERNATIONAL CONGRESS OF CLINICAL PATHOLOGY, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A. Moore, Washington University School of Medicine, St. Louis 10, Mo., U. S. A., Chairman, Committee on Arrangements.

INTERNATIONAL CONGRESS ON DISEASES OF THE CHEST, Barcelona, Spain, Oct. 4-8, 1954. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Ill., U. S. A., Executive Secretary.

INTERNATIONAL CONGRESS ON GROUP PSYCHOTHERAPY, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

INTERNATIONAL CONGRESS ON GYNECOLOGY AND OBSTETRICS, Geneva, Switzerland, July 26-31, 1954. Dr. H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

INTERNATIONAL CONGRESS OF HEMATOLOGY, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6^e, France, Secretary.

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE, Rome and Salerno, Italy, Sept. 13-20, 1954. For information write: Segreteria XIV Congresso Internazionale di Storia della Medicina, Istituto di Storia della Medicina, Citta Universitaria, Rome, Italy.

INTERNATIONAL CONGRESS OF HYDROCLIMATISM AND THALASSOTHERAPY, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni venac 1, Belgrade, Yugoslavia, Secretary General.

INTERNATIONAL CONGRESS OF INDUSTRIAL MEDICINE, Naples, Italy, Sept. 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Polichinico, Naples, Italy, Chairman, Organizing Committee.

INTERNATIONAL CONGRESS OF INTERNAL MEDICINE, Stockholm, Sweden, Sept. 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, Sweden, Secretary-General.

INTERNATIONAL CONGRESS OF INTERNATIONAL COLLEGE OF SURGEONS, São Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

INTERNATIONAL CONGRESS ON MENTAL HEALTH, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY, Buenos Aires, Argentine, April 21-28, 1954. Direccion General de Sanidad Militar, Pozos 2045, Buenos Aires, Argentine.

INTERNATIONAL CONGRESS OF NUTRITION, Amsterdam, Netherlands, Sept. 14-18, 1954. For information write: Dr. M. van Eekelen, Centraal Instituut voor Voedingsonderzoek T.N.O., 61 Catharynesingel, Utrecht, Netherlands.

INTERNATIONAL CONGRESS OF OPHTHALMOLOGY, University of Montreal and McGill University, Montreal, Canada, Sept. 9-11, 1954, and Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 12-17, 1954. Dr. William L. Benedict, 100 First Avenue Building, Rochester, Minn., U. S. A., Secretary-General.

INTERNATIONAL CONGRESS OF ORTHOPEDIC SURGERY AND TRAUMATOLOGY, Berne, Switzerland, Aug. 30-Sept. 3, 1954. For information write: Professor M. Dubois, Isle-Hospital, Berne, Switzerland.

INTERNATIONAL CONGRESS OF PSYCHOLOGY, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N. J., U. S. A.

INTERNATIONAL CONGRESS FOR PSYCHOTHERAPY, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

INTERNATIONAL CONGRESS OF THE SOCIEDAD DE MÉDICOS INTERNOS, Residentes y Becarios del Instituto Nacional de Cardiología de Mexico, Acapulco, Mexico, April 21-24, 1954. For information address: Dr. Jorge Soberón Acevedo, Avenida, Cuauhtémoc No. 300, Mexico, D. F., Mexico.

INTERNATIONAL GERONTOLOGICAL CONGRESS, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

INTERNATIONAL INSTITUTE ON CHILD PSYCHIATRY, Toronto, Canada, Aug. 13-14, 1954. Miss Helen Speyer, International Association for Child Psychiatry, 1790 Broadway, New York 19, N. Y., U. S. A., Executive Officer.

INTERNATIONAL POLIOMYELITIS CONGRESS, Rome, Italy, Sept. 6-10, 1954. Mr. Stanley E. Henwood, 120 Broadway, New York 5, N. Y., U. S. A., Executive Secretary.

INTERNATIONAL SOCIETY OF ANGIOLOGY, North American Chapter, Hotel Mark Hopkins, San Francisco, Calif., U. S. A., June 19, 1954. Dr. Henry Haimovici, 105 East 90th St., New York, N. Y., U. S. A., Secretary.

INTERNATIONAL SOCIETY OF BLOOD TRANSFUSION, Paris, France, Sept. 12-19, 1954. For information write: Colonel Julliard, Société Internationale de Transfusion Sanguine, 53 Boulevard Diderot, Paris 12^e, France.

INTERNATIONAL SOCIETY FOR CELL BIOLOGY, Leiden, Netherlands, Sept. 2-9, 1954. Professor Peter J. Gaillard, University of Leiden, Leiden, Netherlands, Secretary.

INTERNATIONAL SOCIETY OF GEOGRAPHICAL PATHOLOGY, Washington, D. C., U. S. A., Sept. 6-10, 1954. Professor Fred C. Roulet, Hebelstrasse 24, Basle, Switzerland, Secretary-General.

IRISH MEDICAL ASSOCIATION, Killarney, Ireland, July 7-10, 1954. Dr. P. J. Delaney, 10, Fitzwilliam Place, Dublin, Ireland, Medical Secretary.

JOURNEES MEDICALES, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geoffroy, Colombes (Seine) France.

LATIN AMERICAN CONGRESS ON GYNECOLOGY AND OBSTETRICS, Sao Paulo, Brazil, July 10-15, 1954. Prof. Dr. Jairo Ramos, av. Brigaderio Luiz Antonio, 278-8^o andar, Sao Paulo, Brazil, Chairman of Organizing Committee of Medical Congresses.

LATIN AMERICAN CONGRESS ON MENTAL HEALTH, Sao Paulo, Brazil, July 17-22. For information address: Professor A. C. Pacheco e Silva, Avenida Brigaderio Luiz Antonio 651, Sao Paulo, Brazil.

LATIN AMERICAN CONGRESS OF OTORHINOLARYNGOLOGY, Caracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro, Medico, Caracas, Venezuela, Secretary-General.

LATIN AMERICAN CONGRESS OF PHYSICAL MEDICINE, Medellin, Columbia, South America, Feb. 15-20, 1954. Dr. Cassius Lopez de Victoria, 176 East 71st St., New York 21, N. Y., U. S. A., Executive Director.

PAN AMERICAN CONGRESS OF CHILD WELFARE AND PEDIATRICS, Sao Paulo, Brazil, July 15-21, 1954. For information address: Dr. Jairo Ramos, Avenida Brigaderio Luiz Antonio 278-8^o andar, Sao Paulo, Brazil.

PAN AMERICAN CONGRESS OF GASTROENTEROLOGY, Sao Paulo, Brazil, July 19-24, 1954. For information address: Dr. Jairo Ramos, Avenida Brigaderio Luiz Antonio 278-8^o andar, Sao Paulo, Brazil.

PAN AMERICAN CONGRESS OF OPHTHALMOLOGY (Interim), São Paulo, Brazil, June 17-21, 1954. Dr. Moacyr E. Alvaro, Consolacao 1151, São Paulo, Brazil, President.

PAN AMERICAN CONGRESS OF OTORHINOLARYNGOLOGY AND BRONCHESOPHAGOGY, Mexico, D.F., Mexico, Feb. 28-March 4, 1954. Dr. Maximo Garcia Castañeda, Humboldt 17, Mexico 1, D.F., Mexico, Secretary-General.

PAN AMERICAN CONGRESS OF VETERINARY MEDICINE, Sao Paulo, Brazil, April 3-10, 1954. Dr. Joao Soares Veiga, Rua Pires da Mota 159, Sao Paulo, Brazil, Chairman of Organizing Committee.

PAN-PACIFIC SURGICAL CONGRESS, Honolulu, Hawaii, Oct. 7-18, 1954. Dr. F. J. Pinkerton, Suite 7, Young Bldg., Honolulu 13, Hawaii, Director General.

SECTIONAL MEETING, AMERICAN COLLEGE OF SURGEONS, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

SOUTH AMERICAN CONGRESS OF ANGIOLOGY, Sao Paulo, Brazil, July 1954. For information write: Dr. Rubens Carlos Mayail, Rua Senador Vergueiro 73, Rio de Janeiro, Brazil, S. A.

WORLD CONGRESS OF CARDIOLOGY, Washington, D. C., and Bethesda, Md., U. S. A., Sept. 12-17, 1954. Dr. L. W. Gorham, 44 East 23d St., New York 10, N. Y., U. S. A., Secretary-General.

WORLD CONGRESS OF INTERNATIONAL SOCIETY FOR THE WELFARE OF CRIPPLES, Scheveningen-The Hague, Netherlands, Sept. 13-17, 1954. Secretariat: Miss H. P. Post, Pieter Lastmarkade 37, Amsterdam Z, Netherlands.

WORLD FEDERATION OF OCCUPATIONAL THERAPISTS, Edinburgh, Scotland, August 17, 1954.

WORLD MEDICAL ASSOCIATION, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Various Centers, July 16. Final date for filing applications in Jan. 16. Sec., Dr. Curtiss B. Hickox, 80 Seymour St., Hartford 15.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written*. Various centers, Sept. 2. *Oral*. Ann Arbor, Oct. 15-18. To be eligible candidates must have completed thirty-six months of training by October 1. Final date for filing application is May 1. Exec. Sec., Miss Janet Newkirk, 66 East 66th St., New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral*. Chicago, April 1-3 (candidates in the midwest). Los Angeles, June 15-17 (candidates west of the Rocky Mountains and west coast). The closing date for acceptance of applications for Chicago and Los Angeles was Feb. 1. New York, Sept. 22-24 (candidates on the east coast). The closing date for acceptance of applications will be April 1. *Written*. Oct. 18. Final date for acceptance of applications will be May 1. *Subspecialties*. *Cardiovascular Disease*. Chicago, April 1. *Gastroenterology*. Chicago, April 2-3. The closing date for acceptance of applications for the subspecialties was Jan. 15. Exec. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral*. Chicago, May or June. Final date for filing application was Jan. 15. Sec., Dr. Leonard T. Furlow, 600 S. Kingshighway, St. Louis 10.

AMERICAN BOARD OF NEUROLOGY AND PSYCHIATRY: *Psychiatry and Neurology*. Chicago, April 29-30. Final date for filing application was Feb. 1. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination* (Part I) and review of case histories for all candidates will be held in various cities of the United States, Canada, and military centers outside the continental United States on Feb. 5. Case abstracts to be sent by the candidate to the Secretary are now due. *Part II*. Chicago, May 10-17. Final date for filing application is April 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

AMERICAN BOARD OF OPHTHALMOLOGY: *Practical examinations, 1954*. San Francisco, June 25-29; New York City, Dec. 5-9. Final date for filing applications was July 1, 1953. *Written, 1955*. Various cities, Jan. 24-25. Final date for filing application is July 1, 1954. *Practical examinations, 1955*. Philadelphia, June 10-15; Chicago, Oct. 9-14. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral*. Boston, May 17-21. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PATHOLOGY: San Francisco, June 17-19. Sec., Dr. William B. Wartman, 303 E. Chicago Ave., Chicago 11.

AMERICAN BOARD OF PEDIATRICS: *Oral*. Washington, D. C., Feb. 19-21; Des Moines, March 19-21; New York City, May 1-3; San Francisco, June 25-27; Chicago, Oct. 8-10 and New Haven, December.

AMERICAN BOARD OF PHYSICAL MEDICINE AND REHABILITATION. *Oral and Written*. Washington, D. C., Sept. 5-6. Final date for filing applications is March 31. Sec., Dr. Earl C. Elkins, 30 N. Michigan Ave., Chicago.

AMERICAN BOARD OF PLASTIC SURGERY: *Entire Examination*. Galveston, April 17-19. Final date for receipt of case reports was Jan. 1. Final date for receipt of case reports for the fall 1954 examination is June 1, 1954. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

AMERICAN BOARD OF PROCTOLOGY: *Part I*. Kansas City, Philadelphia and San Francisco, May 8. Sec., Dr. Louis A. Buie, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 13-14; New Orleans, Feb. 28-March 1, 1955; San Francisco, Mid-October, 1955; New York City, December, 1955. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minnesota.

AMERICAN BOARD OF RADIOLOGY: *Oral*. Spring 1954. Final date for filing application was Dec. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Oral-clinical and pathology*. Chicago, Feb. 17-20. Sec., Dr. Harry Culver, 30 Westwood Road, Minneapolis 16.

BOARD OF THORACIC SURGERY: *Written*. Various centers throughout the country, Feb. 26. Final date for filing application was Jan. 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Street, Detroit, Mich.

DEATHS

Lutterloh, Charles Hartzell ☉ Hot Springs National Park, Ark.; born in Jonesboro, Ark., Oct. 13, 1897; Tulane University of Louisiana School of Medicine, New Orleans, 1921; associate clinical professor of medicine, University of Arkansas School of Medicine in Little Rock; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past president of the Garland County Medical Society, Arkansas State Board of Medical Examiners, and the Mid-South Post Graduate Assembly; member of the American Society for Clinical Investigation, New York Academy of Sciences, American Society for the Study of Arteriosclerosis, American Diabetes Association, American Heart Association, American Geriatrics Association, American Rheumatism Association, and the American Association for the Advancement of Science; during World War I a private in the Student Training Corps, University of Arkansas, Lafayette; discharged on Nov. 26, 1918; became assistant surgeon in the U. S. Harper, Russell Lowell, Yoakum, Texas; Meharry Medical College, Nashville, Tenn., 1916; died Nov. 21, aged 60, of a heart attack.

Hiett, Alva ☉ Monmouth, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; died in the Monmouth Hospital Dec. 10, aged 77, of diverticulum of the esophagus.

Horner, Erwin ☉ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1909; on the staff of the Mount Sinai Hospital, where he died Nov. 8, aged 69, of carcinoma of the prostate.

Howard, Merle Quest ☉ Fort Steilacoom, Wash.; University of Oklahoma School of Medicine, Oklahoma City, 1916; member of the State Medical Society of Wisconsin and the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology; served during World War I; on the staff of the Western State Hospital; died Dec. 5, aged 62.

Howell, Francis Musgrave ☉ Hopewell, Va.; University of London Faculty of Medicine, England, 1908; accidentally drowned Nov. 28, aged 77, when he fell from his motor sailboat.

Imhoff, Robert Ernst ☉ Camden, N. J.; Jefferson Medical College of Philadelphia, 1927; served during World War II; member of the staffs of Cooper Hospital in Camden, Burlington County Hospital in Mount Holly, and Zurbrugg Memorial Hospital in Riverside; died Dec. 20, aged 53, of coronary occlusion.

Jackson, Lawrence Waters, Washington, D. C.; Howard University College of Medicine, Washington, D. C., 1919; died in Freedmen's Hospital Jan. 2, aged 59, of hypertensive arteriosclerotic cardiovascular disease.

Ledesma, Serapion Buenafe ☉ Salinas, Calif.; University of Nebraska College of Medicine, Omaha, 1932; served during World War II; died Nov. 18, aged 53.

Lehmer, Elizabeth E. ☉ Vinita, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1920; for many years on the staff of the Eastern State Hospital; died Nov. 13, aged 66, of carcinoma of the liver.

Leonard, John Edwin ☉ Harford Mills, N. Y.; Long Island College Hospital, Brooklyn, 1889; served as county coroner and as health officer of the town of Harford; died in Johnson City Dec. 8, aged 86, of arteriosclerosis and diabetes mellitus.

Lopatin, Edward ☉ San Francisco; Boston University School of Medicine, 1929; member of the Massachusetts Medical Society; served during World War II; died in the Memorial Hospital, Worcester, Dec. 18, aged 50, of glioblastoma of the brain.

McKinley, Charles Robert ☉ Brewster, Wash.; University of Oregon Medical School, Portland, 1901; in the spring of 1951 McKinley Memorial Hospital was dedicated in his name in Brewster; died Dec. 5, aged 80, of cirrhosis of the liver.

Mason, Frederick C., Massena, N. Y.; McGill University Faculty of Medicine, Montreal, Canada, 1902; died recently, aged 76, of coronary occlusion.

Mason, George Edward, Grand Island, Neb.; Lincoln Medical College, Eclectic, 1917; died Oct. 27, aged 82, of carcinoma of the liver.

Miller, Orden Eugene ☉ York, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1941; served overseas during World War II; died in the York Hospital Nov. 30, aged 43, of pulmonary embolism.

Murray, John Hamilton ☉ Carrollton, Ohio; Chicago College of Medicine and Surgery, 1916; past president of the Carroll County Medical Society; served in France during World War I; affiliated with Mercy Hospital in Canton; died Nov. 29, aged 63, of pulmonary thrombosis.

Myers, Judson William ☉ Postville, Iowa; State University of Iowa College of Medicine, Iowa City, 1915; served during World War I; died Dec. 16, aged 64, of coronary occlusion.

Nelson, Ole C., ☉ Chicago; Chicago Medical School, 1920; for many years assistant warden and for 12 years medical director of the Cook County Hospital, where he retired in June, 1953; familiarly known as "Mr. County Hospital"; died in his home in Oak Park, Ill., Jan. 16, aged 72, of coronary thrombosis.

Nicholson, Plummer A., Washington, N. C.; College of Physicians and Surgeons, Baltimore, 1889; formerly vice-president of the Seaboard Medical Association; died Nov. 28, aged 88, of senility.

Nock, Randolph Maxwell, Salisbury, Md.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1925; fellow of the American College of Surgeons; affiliated with Peninsula General Hospital; died in the University Hospital, Baltimore, Dec. 15, aged 51.

Osborne, Fielden L., Rugby, Va.; University of Louisville (Ky.) Medical Department, 1894; died Oct. 7, aged 83, of uremia.

O'Sullivan, Anna ☉ Boston; Tufts College Medical School, Boston, 1910; served as secretary of the Massachusetts Women's Medical Society; affiliated with New England Hospital for Women and Children; died Nov. 18, aged 77, of a heart attack.

Payzant, Claude Louis ☉ Boston; Boston University School of Medicine, 1910; past president of the New England Physical Therapy Society; served on the staff of the Quincy (Mass.) City Hospital; died Dec. 5, aged 66, of heart disease.

Phipps, Zack Glenn, Galax, Va.; Tennessee Medical College, Knoxville, 1900; died Oct. 29, aged 77, of brain tumor and chronic bronchiectasis.

Plunkett, Randolph S., Picayune, Miss.; Memphis (Tenn.) Hospital Medical College, 1910; died in Touro Infirmary, New Orleans, Dec. 26, aged 78.

Porter, Robert Fulton ☉ Middlesboro, Ky.; University of Louisville (Ky.) School of Medicine, 1929; served during World War II; formerly health officer of Grayson County; died Dec. 31, aged 53.

Powell, Leo M., New York City; New York Homeopathic Medical College and Flower Hospital in New York, 1915; died in Mount Sinai Hospital Oct. 11, aged 70.

Reed, Jewett Villeroy ☉ Indianapolis; Johns Hopkins University School of Medicine, Baltimore, 1904; assistant professor emeritus of surgery at Indiana University School of Medicine; fellow of the American College of Surgeons; served during World War I; on the staff of the Methodist Hospital; died Dec. 4, aged 75, of pneumonia.

Reeser, Norman Brandt, Camp Hill, Pa.; College of Physicians and Surgeons, Baltimore, 1912; served on the staff of the Lancaster (Pa.) General Hospital; died Dec. 16, aged 66, of coronary thrombosis.

Rice, William Frederick, Lieut. Col., U. S. Army, retired, Fresno, Calif.; born in Salisbury, N. C., June 21, 1885; University of Maryland School of Medicine, Baltimore, 1914; served during World War I; entered the regular army as a first lieutenant June 14, 1916; promoted to lieutenant colonel May 26, 1936; retired Oct. 31, 1939 for disability in line of duty; medical director of the California Industrial Safety Center; fellow of the American College of Physicians; died Dec. 14, aged 68, of heart disease.

Ricketts, Wilbur Anthony ☉ Dayton, Ohio; Ohio State University College of Medicine, Columbus, 1923; past president of the Montgomery County Medical Society, and the Dayton Obstetrical Society; fellow of the American College of Surgeons; affiliated with St. Elizabeth Hospital, Good Samaritan Hospital, and the Miami Valley Hospital, where he died Dec. 28, aged 57, of cerebral thrombosis.

Rosburg, August Henry ☉ San Francisco; Rush Medical College, Chicago, 1912; died Nov. 29, aged 70, of coronary thrombosis.

Rose, Samuel ☉ New York City; Long Island College Hospital, Brooklyn, 1908; a draft board medical examiner during World Wars I and II; died in the Mount Sinai Hospital Dec. 22, aged 70, of coronary heart disease.

Saffer, Delbert Thornton ☉ Middleburg, Va.; Medical College of Virginia, Richmond, 1930; president of the Loudoun County Medical Society; deputy coroner of Loudoun County; clinician to Fauquier-Loudoun Health Center; died Dec. 6, aged 48, of coronary thrombosis.

St. John, Byron Douglas ☉ Port Washington, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1921; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; consultant at the North Shore Hospital in Manhasset; attending physician on the staffs of the Nassau Hospital in Mineola, Meadowbrook Hospital in Hempstead, and Flower and Fifth Avenue Hospitals in New York, where he died Dec. 15, aged 58, of coronary disease.

Schaaf, Katherine M., ☉ St. Louis; Barnes Medical College, St. Louis, 1905; died Nov. 8, aged 78.

Schlesselman, George Herman ☉ Minneapolis; the Hahnemann Medical College and Hospital, Chicago, 1913; on the staff of the Swedish Hospital, where he died Nov. 3, aged 68, of adenocarcinoma of the rectum.

Seligmann, Erich, New York City; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1904; fellow of the American Public Health Association; affiliated with Beth Israel Hospital, where he died Jan. 1, aged 73, of cerebral hemorrhage.

Shell, Roy Adeson, Chicago; Meharry Medical College, Nashville, Tenn., 1915; died Dec. 13, aged 66, of hypertensive heart disease.

Smith, DeVerne Churton ☉ Flint, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; affiliated with St. Joseph Hospital and Hurley Hospital, where he died Dec. 17, aged 73, of hemorrhage from duodenal ulcer.

Smith, George Chester, Monrovia, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; died Dec. 4, aged 74, of coronary occlusion.

Smith, Paul Ruskin ☉ Wilmington, Del.; Jefferson Medical College of Philadelphia, 1907; past president of the New Castle County Medical Society; formerly vice-president of the Medical Society of Delaware; for many years surgeon for the city bureau of police; affiliated with the Delaware Hospital, where he died Dec. 5, aged 69, of cerebral hemorrhage.

Sommer, Karl Moritz ☉ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1930; on the staff of Mount Sinai Hospital; died Dec. 26, aged 49, of cancer.

Stanton, Joseph ☉ Boston; Harvard Medical School, Boston, 1903; fellow of the American College of Surgeons; visiting surgeon, Newton-Wellesley Hospital in Newton Lower Falls; surgeon and for many years chief of staff, St. Elizabeth's Hospital, where he was a trustee; died Jan. 2, aged 75.

Steere, Frederick Eugene ☉ Claremont, Va.; Medical College of Virginia, Richmond, 1909; also a graduate in pharmacy; died in St. Luke's Hospital, Richmond, Nov. 29, aged 83, of coronary thrombosis.

Stookey, Lionel Jerome, San Francisco; Tulane University of Louisiana School of Medicine, New Orleans, 1924; on the staff of the Mary's Help and St. Francis hospitals; died Dec. 1, aged 62, of myeloma and coronary occlusion.

Swindell, Charles LeRoy, Kecoughtan, Va.; University of Maryland School of Medicine, Baltimore, 1909; died in Hampton Oct. 12, aged 69, of bronchogenic carcinoma with widespread metastases.

Tennent, Gaillard S., ☉ Asheville, N. C.; North Carolina Medical College, Davidson, 1894; past president of the Buncombe County Medical Society; served during World War I; died Oct. 29, aged 81, of carcinoma of the pancreas.

Thearle, William Henry ☉ Albuquerque, N. Mex.; College of Physicians and Surgeons, Baltimore, 1908; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; member of the American Association of Thoracic Surgery, American College of Chest Physicians, and the American Trudeau Society; at one time an officer in the regular army; member of the staff, Southwestern Presbyterian Sanatorium and St. Joseph Sanatorium and Hospital; died Dec. 3, aged 69.

Thomas, Llewelyn Ivor ☉ Akron, Ohio; Jefferson Medical College of Philadelphia, 1912; captain, Medical Corps, U. S. Army during World War I; venereal disease control officer, Akron Municipal Health Department; affiliated with the City Hospital; died Nov. 10, aged 66, of coronary occlusion.

Travis, Daniel J., Eddyville, Ky.; University of Louisville (Ky.) Medical Department, 1901; member of the county board of health; died Dec. 21, aged 80, of cerebral hemorrhage.

Tripp, Edwin Prescott ☉ Falmouth, Mass.; Tufts College Medical School, Boston, 1910; for many years associate medical examiner; died Dec. 11, aged 77, of carcinoma of the sigmoid colon.

Tunstead, Hugh John ☉ Minneapolis; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1901; formerly on the faculty of his alma mater; served on the staff of the Minneapolis City Hospital; died in the Eitel Hospital Nov. 29, aged 77, of arteriosclerotic heart disease.

Tyler, George Colbert, Newport News, Va.; University of Tennessee College of Medicine, Memphis, 1924; city health officer from 1927 to 1941; served during World War I; consultant for Chesapeake and Ohio Railroad Company; member of the medical staff, Newport News Shipyard and Dry Dock Company; on the staff of the Riverside Hospital; died in a Chesapeake and Ohio train coach in Richmond Nov. 21, aged 55, of coronary arteriosclerosis.

Tyson, Forrest Clark, Manchester, Maine; Tufts College Medical School, Boston, 1905; member of the American Psychiatric Association and the New England Society of Psychiatry, of which he was past president; assistant superintendent of the Bangor State Hospital from 1907 to 1913, when he became superintendent of the Augusta State Hospital, serving until 1946; died Dec. 25, aged 71, of acute coronary disease.

Ullman, Albert Eckhardt, North Babylon, L. I., N. Y.; Columbia University College of Physicians and Surgeons, New York, 1899; for many years on the staff of the Central Islip State Hospital; served on the staffs of the Kings Park (N. Y.) State Hospital and the Willard Parker Hospital in New York; died in Nassau-Suffolk General Hospital in Copiague Nov. 24, aged 79, of lobar pneumonia.

Wearne, Frederick John ☉ Omaha; John A. Creighton Medical College, Omaha, 1898; an Associate Fellow of the American Medical Association; past president of the Omaha-Douglas County Medical Society; served on the staffs of St. Joseph's and St. Catherine's hospitals; died Dec. 5, aged 79, of arteriosclerosis.

Webb, Frank Reed, Los Angeles; Columbia University College of Physicians and Surgeons, New York, 1902; formerly chief autopsy surgeon, county coroner's office; died in the Hollywood Presbyterian Hospital Dec. 7, aged 76, of arteriosclerotic heart disease.

Wehman, Edward John ☉ Burlington, Iowa; St. Louis University School of Medicine, 1905; member of the Radiological Society of North America; served overseas during World War I; formerly health officer; affiliated with Burlington Hospital; died Dec. 5, aged 73, of coronary thrombosis.

Wells, Donald Breckenridge ☉ Hartford, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1912; member of the founders group of the American Board of Surgery; member of the New England Surgical Society; fellow of the American College of Surgeons; served during World War I; affiliated with Bristol (Conn.) Hospital, J. J. McCook Memorial Hospital, Institute of Living, and the Hartford Hospital, where he died Dec. 22, aged 69, of carcinoma.

Whitehill, Nelson McPhee ☉ Boone, Iowa; Rush Medical College, Chicago, 1897; died Nov. 14, aged 83, of coronary occlusion.

Wiggers, Henry Hamilton ☉ Cincinnati; Pulte Medical College, Homeopathic, Cincinnati, 1892; at one time secretary-treasurer of his alma mater; fellow of the American College of Surgeons; formerly a member of the city health department; served as president of the Wiggers Realty Company, as director of the City Hall Bank, and as president of the Cincinnati Lyceum; affiliated with Bethesda Hospital, where he was past chief of staff and where he died Dec. 23, aged 84.

Williams, Arthur Maurice ☉ White Plains, N. Y.; University and Bellevue Hospital Medical College, New York, 1925; chairman of the executive committee of the National Association for the Advancement of Colored People; on the staff of St. Agnes Hospital, where he died Nov. 17, aged 56, of coronary occlusion.

Wilson, Dale ☉ Toledo, Ohio; Toledo Medical College, 1901; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served during the Spanish-American War and World War I; affiliated with Toledo, St. Luke's, and Maumee Valley hospitals, and the Mercy Hospital, where in 1949-1950 he was chief of staff and where he died Dec. 14, aged 75, of cardiorenal vascular disease.

DIED WHILE IN MILITARY SERVICE

Withers, Samuel Meacham Jr., ☉ Moultrie, Ga.; born in Chadbourne, N. C., Jan. 30, 1905; Medical College of Georgia, Augusta, 1935; interned at Piedmont Hospital in Atlanta, where he was a resident; served during World War II; honorably relieved from active duty on Nov. 22, 1945; returned to active duty in the Army, October, 1950; stationed at Fort Benning, Ga., until July, 1952; at the time of his death was serving as a major in the Medical Corps, Officers Reserve Corps, in charge of the 548th General Dispensary in Korea, where he died June 19, 1953, aged 48, of myocardial infarction.

GOVERNMENT SERVICES

ARMY

Major Lee Wins Sportsmanship Trophy.—Major Samuel Lee, San Francisco, of the U. S. Army Medical Corps, 1948 and 1952 Olympic diving champion, has been named winner of the 1953 James E. Sullivan memorial trophy. The award, made by the National Amateur Athletic Union, goes annually to "the amateur athlete who by performance, example, and good influence, did most to advance the cause of good sportsmanship during the year." Dr. Lee was born in California and served as an enlisted man during World War II. He became a regular Army medical officer July 27, 1949, after having served as a medical officer in the U. S. Army since June 16, 1946.

Personal.—Major Gilbert J. Vosburgh, professor of obstetrics and gynecology at Western Reserve University, Cleveland, before his call to active duty, has been assigned to the Army Surgical Research Unit at Brooke Army Medical Center, Fort Sam Houston, Texas.

NAVY

Training Course in Isotopes.—The third annual training course in special weapons, isotopes, and military medicine presented by the district medical and dental officers of the 12th naval district will be conducted at the Naval Station, Treasure Island, San Francisco, March 1-5. The course will provide reserve and regular medical department officers with information concerning the many aspects of special weapons, isotopes, and military medicine and dentistry. Naval Reserve Medical, Dental, Medical Service, Nurse, and Hospital corps officers residing in the 11th, 12th, and 13th naval districts who desire to attend this course in a pay status should submit their requests for active duty for training to their naval district commandants at an early date. Active duty medical department officers may be given authorization orders, at no expense to the government, in accordance with current instructions. Government transportation between Treasure Island and the Federal Office Building, San Francisco, will be furnished at 8 a. m. and 4 p. m. daily.

PUBLIC HEALTH SERVICE

Sewage Treatment Plants.—Construction contracts for 155 projects to aid in the nation's stream pollution abatement efforts, through providing treatment of sewage from municipalities, institutions, and other significant population centers, were awarded during the third quarter of 1953, the U. S. Public Health Service reports. The contracts totaled 38 million dollars and covered 87 new plants and 68 additions, enlargements, or improvements to existing plants.

Of the 87 new plants, only 7 were for places of more than 20,000 population: Jefferson County, Alabama, Kalamazoo, Mich., Middle Rouge Parkway Area, Mich., Knoxville, Tenn. (2 plants), and Weirton, W. Va. (2 plants). More than half of the new plants will serve places of fewer than 5,000 population. Although both the number and the dollar value of contracts for the third quarter are substantially below those for the previous quarter, the totals for the first nine months of 1953 are still about 20% higher than for the comparable period of 1952.

Personal.—Dr. Arthur B. Price has been appointed director of the health resources staff of the Office of Defense Mobilization succeeding Dr. W. H. Aufranc, who has returned to the U. S. Public Health Service. The health resources staff does the staff work for the Health Resources Advisory Committee, which advises the director of the Office of Defense Mobilization on the health resources of the nation and on mobilization planning activities in the health field. Dr. Price, a career officer in the

U. S. Public Health Service since 1934, has been appointed executive secretary of the Health Resources Advisory Committee.—Dr. Henry W. Brosin, professor of psychiatry, University of Pittsburgh Medical School, and director, Western Psychiatric Institute and Clinic in Pittsburgh, has been appointed to serve on the National Advisory Mental Health Council. Except for service in the U. S. Army Medical Corps during World War II, Dr. Brosin has devoted his career to teaching psychiatry, first as instructor in psychiatry and then as professor of psychiatry and head of the division of psychiatry at the University of Chicago Medical School.

Guest Lecturer at National Institutes of Health.—The first in the 1954 series of guest lectures of the National Institutes of Health at Bethesda, Md., was sponsored by the National Heart Institute and presented Jan. 14 by Dr. John R. Pappenheimer of the department of physiology of Harvard Medical School, Boston. The subject was "Ultrafiltration and Diffusion Through Biological Membranes." This lecture opened the second series. Each year eight lectureships are awarded by the office of the director and the seven research institutes that comprise the National Institutes of Health.

VETERANS ADMINISTRATION

Hospital News.—Dr. Asa B. Friedmann, radiationtherapist of Brooklyn, lectured on the scope of radiation therapy at the VA Hospital, Newington, Conn., Dec. 17, 1953.—Dr. Daniel Blain, medical director, American Psychiatric Association, Washington, D. C., discussed "Administrative Phases of the Treatment Process" before the members of the hospital staff of the Veterans Administration Hospital, Northport, N. Y., Jan. 14.—Dr. Kenneth E. Appel, professor of psychiatry, University of Pennsylvania School of Medicine, Philadelphia, and President of the American Psychiatric Association, lectured on psychotherapy at the VA hospital at Downey, Ill., Feb. 3.

MISCELLANEOUS

Technicians for Overseas Assignments.—Under President Eisenhower's Reorganization Plan No. 7, the responsibility for worldwide technical programs, formerly conducted by several U. S. government agencies, was centralized in the Foreign Service Institute of the Department of State, under the Director of Foreign Operations, Harold E. Stassen. The F. O. A. has just announced that 23 technicians from various states have completed a three week orientation course at the institute and are ready to take assignments with overseas missions. This course emphasizes the customs, language, and history of the people among whom the technicians will live and work, sharing their skill and knowledge, and showing them how to develop their own resources and abilities. This course has now been given to 30 such groups who are serving in 56 countries. These groups include specialists in, among other things, parasitology, medical entomology, public health, sanitation, nursing, and social welfare. Among the 23 who have just completed this course and are ready for assignment are Dr. Arthur C. Curtis of Little Rock, Ark., director, division of tuberculosis control, Arkansas State Board of Health, who will join the mission in Ethiopia; Deward E. Waggoner, Ph.D., of Portland, Ore., formerly a commissioned officer in the U. S. Public Health Service and director of public health statistics of the Kansas State Board of Health, who will join the mission in Egypt as a medical and public health statistician; and Joseph E. Alicata, Ph.D., of Honolulu, Hawaii, formerly a zoologist with the U. S. Department of Agriculture and for many years with the University of Hawaii, Agricultural Experiment Station, who will join the operations mission in Jordan, where he is scheduled to serve with the central laboratory at Amman.

FOREIGN LETTERS

BELGIUM

Aeromedical Association.—The French-speaking branch of the Aeromedical Association met in Brussels in September. General Bergeret (France) and Major Wiesinger (Switzerland) each reported on fatigue in jet pilots. General Bergeret in summarizing the discussion said that the fatigue of jet pilots is not essentially different from that of pilots of airplanes with reciprocating engines. It is a complex mixture of mental and emotional factors. It is possible to avoid the overexcited stage by providing for total recuperation based on healthy relaxation, sufficient sleep, and a moderate program of sports after each flight or day of flying. Major Wiesinger with the cooperation of General Bergeret and Major Evrard (Belgium) reported on the problem of aging in military pilots. There is no evidence that either military or civilian pilots show signs of aging earlier than persons in other occupations, and it does not seem feasible at present to formulate rigid rules governing retirement. Every case must be judged on its merits. The next meeting will be held in Zurich in September, 1954.

Alcoholism and Criminality.—At a meeting of the Legal Medicine Society of Belgium in October, 1953, Alexander reported on 12 crimes or misdemeanors, ranging from murder to minor infractions of the law. In every case, the guilty person was arrested or gave himself up to the police immediately after the act and alcoholism was found to be a causative factor in all these acts. Although a blood alcohol determination was only rarely made in such cases, it was the consensus that it should be extended to these cases and not limited, as at present, to persons involved in automobile accidents. A clinical examination of these persons should also be made as soon as possible. In certain cases it would also be advantageous to examine the victim. The characteristics presented by certain subjects suspected of a toxicomania other than alcoholism should also be noted. These things would not only clarify individual situations but also reveal any relation that may exist between the amount of alcohol in the blood and certain types of crime.

LONDON

New Hospital Building.—So few new hospital buildings have been built since the end of the war in Great Britain that it is of interest to note the opening of a new outpatient department at St. James' Hospital in southwest London, a former municipal hospital. Built at a cost of £200,000, it has been described as "the most modern in the world." The structure of the building consists of a shell of brick piers and especially strong glass. Almost the only other fixed parts are the cork-tiled floors and the interior piers. The laminated plastic partition walls are all removable. In other words, the whole building can be reorganized within a few days for other purposes. It consists of two blocks. In the north block, the entrance hall, lounge, and administrative offices are on the ground floor, with the ear, nose, and throat and eye clinics above and the chest clinic below. In the south block, the ground floor is given over to the orthopedic and gynecologic clinics, with the medical clinics on the first floor and the surgical clinics on the top floor.

Schools for Maladjusted Children.—"The present situation of schools for maladjusted children seems so deplorable, and so likely to discredit their value, that it requires discussion" is the view expressed by Dr. W. Mary Burbury in a recent article in *Lancet* (2:1251, 1953). She advocates that each group of such schools be associated with a hospital unit adequately staffed by "psychiatrically trained personnel." There would be interchange between the hospital and the school, and "the hospital ward might well act as a diagnostic centre as well as a

place for treatment." Teachers might be allowed into the hospital to instruct individual children or very small groups. The school should have a hostel for children ready to try ordinary school life, and for adolescents ready to try a job, but not yet ready to return to their homes. A holiday center or camp is also needed for children unable to return home for holidays. The natural center for such a unit would be a university with a medical school that offers postgraduate training to physicians specializing in child psychiatry and also provides courses for teachers, social workers, and psychiatric social workers. Separate schools would be planned for children of different sex, ages, and intelligence levels and with different types of problems. Staffing should be "generous, hours short, and classes small," and teachers should have special training in the handling of the maladjusted child. Specially trained nurses would also be required in the hospital wards dealing with these children.

Faulty Penicillin Tablets.—Much publicity has been given to a report from Birmingham of an examination of 82 samples of oral penicillin tablets supplied on prescription in Birmingham. Of these tablets, 19 did not comply with the B.P. standard of containing not less than 90% penicillin; 4 showed a deficiency of 22 to 27%, 4 of 33 to 62%, and 4 of 90 to 100%. "This may fairly be interpreted," the analyst comments, "as saying that a patient stands a one in 20 chance of being supplied with tablets entirely devoid of any therapeutic value." Only 22 of the 82 samples were supplied in the makers' original sealed containers, 27 were supplied in stoppered containers other than the original, and 33 were dispensed in cardboard boxes. Eight of the last lot were defective. The four tablets dispensed in one prescription were so wet that they had stuck to each other and to the cardboard container. Another sample was supplied in a cardboard pillbox containing cotton wool to which the tablets, which were a bright yellow instead of white, had partially adhered because of their damp condition. In contrast to this sorry picture, samples purchased direct from the manufacturers were all found to be of full strength. One of the recommendations made by the analyst is that physicians should be encouraged to prescribe penicillin tablets for oral use in numbers equal to the number of tablets contained in a single package, thus rendering it unnecessary to "break bulk."

Teething Powders.—Last year, in reply to a question in the House of Commons, the Minister of Health stated categorically that "the indiscriminate use of teething powders containing mercury is clearly undesirable." Neither mothers nor manufacturers paid any attention to this warning, and the powders continued to be sold in large numbers in the pharmacies of the country, 7 million packages of one popular brand being sold every year. Matters were recently brought to a head in a county where sales were unusually high. In succeeding weeks inquests were held on two infants who had died of a disease attributed to mercurial poisoning as a result of the ingestion of teething powders containing mild mercurous chloride (calomel). The manufacturers of this brand have announced that they have replaced the mercurous chloride with phenolphthalein in their powders. It is now hoped that other manufacturers will follow their example and omit the mild mercurous chloride from their teething powders.

Use and Abuse of Detergents.—An interesting report on the use of detergents, based on an investigation carried out by the London County Council, has been presented to the Royal Sanitary Institute. The Council spends about £35,000 a year on detergents. One of the main conclusions of the report is that there is no direct relation between the efficiency of a detergent and its ability to produce a foam. On the other hand, it was found that if workers were forced to use a mixture with little or no foaming power they were very dissatisfied. "This psychological reaction should not be disregarded, and in consequence good foaming power is required until time and staff are avail-

*The items in these letters are contributed by regular correspondents in the various foreign countries.

able to convince the very large number of washers that this is not necessarily an important factor." The view is expressed that alleged skin conditions attributed to the use of detergents are largely due to their extravagant use. No complaints of dermatitis of the hands had been received during the use of over 1,000 tons of blended synthetic detergent mixtures, a result attributed to control of the amounts of water.

Multiple Sclerosis Society.—A Multiple Sclerosis Society has been founded by a group of lay persons, most of whom have close relatives suffering from the disease. It will follow broadly the form of the National Multiple Sclerosis Society in the United States. It aims at cooperating with the medical profession in encouraging scientific research into the cause and cure of the disease. In addition, it proposes to develop a rehabilitation program for victims of the disease. Members of the society will visit patients and give them help and advice, and, if necessary, financial assistance. It is estimated that disseminated sclerosis attacks one person in 2,000 in Great Britain.

Public Health.—The annual report of the Chief Medical Officer of the Ministry of Health for 1952, dealing with England and Wales (Scotland has its own Department of Health), ranges over a wide field. The estimated population, 43,940,000, is 140,000 greater than 1951, but more interesting is the age distribution: 22% of the population were less than 15, 67% between 25 and 64, and 11% aged 65 and over. The corresponding percentages for 1901 were 32, 63, and 5. It is estimated that 50 years from now there will be as many persons over 65 in the population as there are persons under 15. There was a further fall in the birth rate, from 15.5 per 1,000 population in 1951 to 15.3. The stillbirth rate was 22.7 per 1,000 total live and still births. The death rate at 11.3 per 1,000 was the second lowest ever recorded. The most striking decrease in the death rate was among young women; at ages 15 to 19 a fall from 0.78 per 1,000 in 1950 to 0.51 in 1952, a relative improvement of 35%, and at ages 20 to 24, a fall from 1.09 per 1,000 in 1950 to 0.76 in 1952, a relative improvement of 30%. Most of this improvement is attributed to the decline in deaths from tuberculosis, which used to be responsible for about half of the total deaths in this age group. The expectation of life is now 67 years for males and 72 for females. The number of deaths from respiratory tuberculosis was 22% less than in 1951 and less than half the number in 1948. Deaths from cancer of the lung, however, continued to increase, and three deaths were assigned to cancer of the lung for every two assigned to respiratory tuberculosis. The actual figure (14,218) was only slightly less than that for cancer of the stomach (14,409), which still leads the list of malignant growths in the causes of death. The number of deaths due to coronary disease was 61,429 compared with 40,330 in 1948. The deaths from leukemia continued to increase; there were 2,043 compared with 1,489 in 1948. There were 32 deaths from diphtheria (2,285 in 1932). The infant mortality rate fell again, to 27.6 per 1,000 reported live births, compared with 29.7 in 1951. Among reportable infectious diseases, the more outstanding figures are 372 confirmed reports of diphtheria (658 in 1951); 130 of typhoid (202 in 1951); 1,038 of paratyphoid (1,094 in 1951); and 135 of smallpox (27 in 1951).

Some interesting figures are quoted from the results of the 1951 census of population. The average family size was 1.69. Of married women under 45, 5% had five or more children, compared with 20% in 1911. The population drift from agriculture and from villages to towns continues. Compared with 1931, there are fewer miners, textile workers, and women in domestic service and more builders, clerks, professional workers, and employees in the chemical and engineering occupations. For instance, there were only 178,000 resident domestic servants in private households, compared with 706,800 in 1931.

In the chapter on smallpox it is pointed out that, compared with 1951, the total number of persons vaccinated during 1952 was fewer by over 92,000 and the total number of revaccinations fewer by 210,000. The vaccinia rate for infant vaccination was only 30.6%, but this showed a slight rise over 1950 and 1951. Not more than 1 in 25 of the children entering or leaving school who had been previously vaccinated in infancy were revaccinated. As complications of vaccination, there were 15

cases of generalized vaccinia (two fatal) and six of postvaccinal encephalomyelitis (one fatal). This gives an incidence of generalized vaccinia of 1 per 20,000 primary vaccinations at all ages.

Details are given of an investigation of the effect of ultraviolet light irradiation in schoolrooms on the health of school children. Observations were made in six schools for three years (1946-1948). In three of the schools all classrooms and assembly halls of the infant and junior departments were equipped with ultraviolet lamps to irradiate the air in the upper part of the room and irradiation was maintained during school hours throughout the whole period. There were 1,550 children in the irradiated schools and 1,860 in the control schools. The final results showed that "there was no appreciable effect on the total sickness in either the infant or junior departments."

The following quotation from the section on typhoid is in the best Sherlock Holmes' tradition: "Outbreaks were few and small. In one of these the connexion between the widely scattered cases was established only by elaborate laboratory investigation. The seven patients concerned gave a history of some definite association between their illness and a previous visit to one particular section of the East Anglian coast. In four instances the patients had eaten cockles which they had gathered from the foreshore adjoining the outfall of a small sewage treatment plant; in three instances the patients had bathed in the tidal estuary at the same point. Phage-typing of the cultures derived from these patients showed that all belonged to an 'untypable' Vi-strain giving the same phage reaction. An identical strain of *Salm. typhi* was also isolated from one sample of cockles taken from the foreshore, and at a later date, after numerous specimens of effluent had been examined without result, the same strain of *Salm. typhi* was isolated from a specimen of crude sewage taken at the point of entry of the main sewer into the treatment plant. Particular interest attaches to these cases, because four of them were in visitors from towns far from East Anglia, and it was the results of routine phage typing which directed attention to this one small section of the coast as the place of infection, and established proof of infection from sewage effluent discharging at that point."

The number of new cases of syphilis has fallen to 891 in men and 462 in women, compared with 1,498 in men and 774 in women in 1951. The number of cases of congenital syphilis in infants less than 1 year old fell from 156 in 1951 to 110 in 1952, the lowest figure ever recorded. The number of cases of gonorrhea is rising: 15,510 men and 3,585 women were affected, compared with 14,975 men and 3,089 women in 1951. There has also been an increase in the number of new cases of nongonococcal urethritis in men, from 10,794 in 1951 to 11,552 in 1952. In discussing the present position and the future, the following comments were made: "The fact that, in spite of penicillin and other antibiotics, venereal urethritis in man (both gonococcal and non-specific) as well as gonorrhea in women has increased during 1952 should restrain any tendency to complacency about the venereal diseases position, or any temptation to exaggerate the impact of antibiotics on these diseases." What has occurred with gonorrhea might yet happen with syphilis and the effect on the public health of an increase in nongonococcal urethritis, now recognized as a venereal disease, cannot yet be appreciated. Sexual promiscuity is still rife and so long as this is the case, the danger of venereal disease remains. An analysis of the results of antenatal syphilis testing from six centers shows that, of 103,810 specimens of blood tested, 364 (0.35%) were positive. The figures from two of these centers have been further analyzed according to whether the woman was a primipara or a multipara, and the results show positive tests among 0.25% of the primiparas and 0.6% of multiparas. The comment is made that "these figures, if they are supported from other centers in subsequent years, suggest that blood-testing for syphilis is advisable not only in a first pregnancy but also as a routine in subsequent pregnancies."

The figures for acute rheumatism show "another welcome reduction" in the number of deaths attributed to rheumatic fever, 328, compared with 378 in 1951 and 1,029 in 1943. Supplies of cortisone and corticotropin for the treatment of all forms of rheumatism are still limited; during the year 4,200 National Health Service patients were treated with these substances.

PARIS

Treatment of Gastric Ulcer.—At the meeting of the Medical Society of Paris Hospitals on Oct. 16, 1953, R. Cattani and P. Frumusan reported a treatment for gastric ulcer that was suggested by Dr. Buccaille a few years ago. Their patient, a 74-year-old man, had a large ulcer of the lesser curvature of the stomach. Because the usual forms of treatment did not relieve his severe pain, the authors infiltrated the left frontal lobe of the brain with 15 cc. of procaine. This immediately relieved the pain. A few days later they infiltrated the right frontal lobe, and this was followed by a complete clinical and roentgenologic cure. The authors called attention to two patients with hemorrhagic rectocolitis treated by the same method with good results. They believe that this confirms the corticovisceral theory of the mechanism of gastric ulcer suggested by Bykhow and Kourstine. Although Buccaille, the originator of this method of treatment, obtained good results in 80% of his patients with intractable pain, he stressed the precautions necessary to avoid an injury of the cortex during the operation.

Corticotropic Principle in the Human Placenta.—Although temporary remission during conception of a chronic progressive polyarthritides is common, no appreciable improvement could be obtained in rheumatic patients by giving the sex hormones in a filtrate of urine from a pregnant woman, transfusion of blood taken from a pregnant woman, or placental blood. E. Aron has been able to extract from the human placenta, by treating it with acetone, a corticotropic substance having the same physiological action as corticotropin (ACTH). It cannot yet be produced on a commercial scale.

Peptic Ulcer and Renal Lesions.—For several years Dr. Lambing and his co-workers have tried to find a relationship between peptic ulcer and experimental renal lesions. In the case of ulcer in white rats produced by pyloric ligation, the renal histological lesions are severe. The vascularization of this organ is greatly reduced and ischemia is frequently complete. The authors believe that, in animals submitted to experiments of this sort, renal lesions precede the gastric changes and may even favor them, probably by the secretion of a vasotropic factor formed in the ischemic renal parenchyma.

In the autopsies of five patients who died with gastric ulcer, Lenoir, Richet, and Jaquelin in 1920 found an unsuspected renal sclerosis. At a meeting of the Medical Society of Paris Hospitals in June, 1953, S. Bonfils, J. P. Hardouin, L. René, D. Hewitt, and A. Lambing reported on the histological findings in renal biopsy specimens obtained during 18 operations for peptic ulcer. The removal of such specimens has been shown to be harmless. Nine of the patients had gastric ulcers (five of which were on the lesser curvature), and nine had duodenal ulcers (seven of which were in patients less than 40 years of age; the others were between 40 and 60 years old). In 17 of these patients, chronic interstitial and glomerular nephritis and even tubular lesions showing acute and recent pathological changes were found. The authors stressed the fact that no renal tissue changes have been found in patients with biliary lithiasis, hemorrhagic rectocolitis, or hypertension.

Treatment of Anorexia Nervosa.—At the same meeting of the Medical Society of Paris Hospitals, J. Weil, J. Bernefeld, P. H. Paumelle, and Mlle. Josslow reported the treatment of a patient suffering from anorexia nervosa with isoniazid for one year. If the good results obtained can be duplicated in a larger series, ambulant treatment of these patients can be envisaged, and complete isolation should be necessary only in the severest cases. Even in these isoniazid, by modifying the thymic action, can be considered as an important adjuvant medication.

Arterio-capillaries in Arterial Hypertension.—At Toulouse Neurologic Clinic, Riser, Planque, and Dardennes have studied the arterio-capillary condition in hypertension and especially in the malignant phase. They concluded that, when the total mass of blood and that of the interstitial liquid are not ele-

vated in these patients, the capacity of the vascular system is lowered. On studying the head of a patient with hypertension, the authors stated that the temporal pressure of the retina was proportionally elevated to humoral pressure, causing meningeocerebral and retinal morbid changes. It is necessary to distinguish the local vascular lesions of the retina from exudations on the optic disk. A pathognomonic sign of malignant hypertension before the age of 60 would be the disappearance of the marginal capillary network.

Periodic Affections.—In 1951, Cattani and Mamou reported 14 patients suffering from a syndrome of unknown cause. Most of the patients were young persons who lived in Israel or North Africa. They suffered from an attack of articular rheumatism, fever, or severe abdominal pain, or they had all three at once. The symptoms lasted a few days or a few weeks and then disappeared until the next attack. Of their 14 patients, 10 were of the same family. All clinical and laboratory examinations were normal, except that for albuminuria. At a similar meeting in May, 1953, H. Mamou and A. Bernard reported two more cases of this disease. One patient was a 36-year-old man who was born in Paris and had never left France but whose parents were Algerian Israelites. For 25 years he had had attacks, sometimes resembling malaria and sometimes characterized by severe epigastric pain and vomiting. Treatment with acetarsone, chlortetracycline (Aureomycin), and other drugs gave no relief. The second patient had a lipid nephrosis, this being the major complication of his periodic affection. At the same meeting, F. Signier, M. Zara, J. L. Funck-Brentano, and G. Lagrue reported a patient with the rheumatic form of this periodic disease. Milliez reported two urban subjects and Ravina, two nonoriental subjects. Ravina noted a striking resemblance between this disease and periarthritis nodosa.

Complications of Corticotropin (ACTH) Therapy.—In *Therapie* of 1952 (pages 377-383), Coste reported the complications observed in treating 600 patients with corticotropin (ACTH) or cortisone, chief of which was hypertension. Edema occurs frequently and, contrary to the current opinion, during an advanced stage of the treatment. If the patient, as is often the case, has cardiac decompensation, this edema may endanger his life. Hypercholesterolemia may be observed during treatment with cortisone, for cortisone keeps the adrenal gland at rest. An increase in the toxicity of an infection, a cortisonic abscess at the point of injection, a pneumopathy, peptic ulcer, or the perforation of an already existing ulcer, the appendix, gallbladder, or intestine may occur. A thorough history by systems should be obtained before cortisone is given. Of the 600 patients, a severe psychosis developed in 5 during treatment. Minor complications include tachycardia, insomnia with euphoria, asthenia after prolonged treatment due to the catabolic effect of the hormone on protein metabolism and to a negative potassium balance, and diabetes without acidosis. If the patient was diabetic prior to treatment, the dose of insulin should be increased, because of the insulin resistance of patients with cortisonic diabetes. This insulin resistance disappears as soon as the hormonotherapy is stopped.

In the same issue, R. Turpin reported a rare case of diffuse hepatic steatosis in a 4-year-old child who for three months had had a subacute micrococcic (staphylococcic) infection. Micrococci were found in the urine, feces, and cutaneomucosal lesions. Even those antibiotics active against micrococci in vitro had no effect on the infection, so he was given 0.1 gm. of cortisone per day and oxytetracycline (Terramycin). Within 60 days he received 4.2 gm. of cortisone; his temperature came down; and his general condition was greatly improved. On the fourth day of treatment, his liver became enlarged and a needle biopsy showed a diffuse steatosis without cellular degeneration or interstitial changes. The humoral examination showed 3.05 gm. of total cholesterol, 2 gm. of esterified cholesterol, 12.4 gm. of lipids, and 3.7 gm. of phospholipids. The dose of cortisone was reduced and treatment stopped the 60th day. The child made a complete recovery.

Treatment of Sciatica.—At a meeting of the French League Against Rheumatism in May, 1953, Professor De Seze, and S. H. Jurmand reported the statistics of their unit in the Lariboisière Hospital covering 872 patients with sciatica. In 93, duration was of less than two months, in 50 it was of just two months, and in the rest it was of longer duration. Eleven per cent were operated on. At the same meeting, P. Ravault, Wertheimer, Vignon, and Michel reported on 70 patients with sciatica on whom they operated. Although 25% of these presented no roentgenologic signs, they were found to have herniation of the intervertebral disk. In 75% either a discoid hernia or discoid protrusion was found. Laminectomy was performed on 10%. The authors believe that operation for discoid hernia is justified, but they advise against rhizotomy.

Alcoholism.—At a meeting of the Congress Against Alcoholism in Paris in 1953, Professor Debré stated that the problem hinges not only on education and antialcoholism propaganda, but also on socioeconomic factors. Millions of Frenchmen derive their living from wine production and distillation, and, to fight efficiently against alcoholism, it is necessary to change the agricultural structure of the country. Instead of raising beets and grapes, cereal grains should be cultivated. In France, alcoholism is due chiefly to wine, which is considered as a national drink and not as an alcoholic beverage; but research has shown that this drink may lead to alcoholism. Professors G. Laroche and Tremolières discussed the food value of alcohol that contains 7 calories per gram. These calories are not used for muscular work and thermal regulation. E. Chabrol and A. Girauld reported that from 1906 to 1940 about 85 cases of cirrhosis of the liver a year have been treated in one hospital in Paris. There was a marked decrease during the war and a corresponding increase after the war. About 30% of these patients are women. They emphasized that alcoholism produces 60% of the cases of cirrhosis.

SWEDEN

Malpractice Suits.—"Läkarnas Ansvarighetsnämnd" (Doctors' Liability Committee) is an official body that deals with claims for compensation against doctors, and its rulings are usually final. In spite of the monotony with which such claims recur year after year, they make instructive reading for the younger generation of physicians. The following two cases, taken from the Dec. 4, 1953, issue of *Svenska Läkartidningen*, are good examples of a happy and an unhappy outcome. After a preliminary radiological screening a physician attempted to induce an artificial pneumothorax in a patient. At the first puncture the manometer showed no movement, and the physician therefore did not introduce any air. The patient complained of pain and of feeling giddy. At the second puncture, the manometer showed normal movements, and air was introduced into the pleural cavity. After spontaneous aspiration had proceeded for some time, the insufflation was completed under positive pressure. This provoked no complications at the moment, but, when the patient sat up, she suddenly felt very giddy, and, though she rallied somewhat after a short interval, her condition was such that she had to be hospitalized. After some initial improvement, her condition became stationary, with signs of involvement of the nervous system probably due to air embolism. The Doctors' Liability Committee ruled that this mishap cannot always be avoided and that the doctor concerned was not guilty of carelessness or neglect. The other case concerned a woman who died shortly after being given an injection of a local anesthetic in the course of an operation for goiter. The anesthetist, a nurse, gave her an injection of a 2% instead of a .1% solution of lidocaine, although she knew at the time that the solution ought to be of the weaker strength. As the surgeon failed to verify the strength of the solution, it was ruled that he, as well as the nurse, was to blame, and they were called on to share equally in the allotted responsibility. It is such a ruling as this that raises the prestige of the tribunal in question, as it refutes the old complaint that physicians side blindly with one another when the honor of their profession is impugned.

Salmonellosis and Poliomyelitis Epidemics.—A report presented to the Swedish Parliament in November, 1953, showed what a great strain salmonellosis and poliomyelitis imposed on the public health authorities in that year. There are about 30 different types of *Salmonella* in Sweden, but only *S. schottmülleri* is known to provoke serious typhoid-like disease. During the five year period 1948 to 1952 salmonellosis remained within modest limits with a maximum of 360 reported cases in one year and a minimum of 129 in another year. In the first five months of 1953 only 38 cases, scattered over the whole of the country, were reported. In the first half of June, 32 cases were reported, but, from June 16 to August 31, there were 7,717 cases, with a concentration in one or two counties, although the whole county was involved. There were 90 deaths from salmonellosis during this period. The incidence declined in September, and only 176 cases were reported in October. The shortage of hospital accommodation was so great at the height of the epidemic that more than half the patients had to be treated at home. No wholesale vaccination was undertaken, and it is doubtful if much would have been achieved by it at the time, because after vaccination immunity takes about three weeks to develop. This epidemic demonstrated the need for regional bacteriological laboratories. The Ministry of Health has recommended the creation of two such laboratories designed to cope with future outbreaks. This epidemic was still raging when a severe outbreak of poliomyelitis occurred. It had, however, been anticipated. During the previous decade an average of 1,550 cases per year had been reported, but, in 1953, by the end of Oct. 3,882 cases had already been reported, of which 2,247 were paralytic; 110 of the patients died. Gamma globulin was given on a very modest scale, for at the time the annual production of it in Sweden did not exceed 4,000 protective doses, and to have increased this supply effectively would have encroached on the available supply of blood for transfusions. With an adequate supply of poliomyelitis virus, it is hoped that in a couple of years vaccination of all susceptible persons against poliomyelitis will be possible. A program of poliomyelitis vaccination will be started this year.

Poisoning by Soporifics.—A revolution in the treatment of poisoning by soporifics is reported by Drs. Arne Aldman, Tore Ekstrand, and Bendt Eyrich, in *Svenska Läkartidningen* for Dec. 18, 1953. This report comes from the Serafimer Hospital, where in the period 1947 to 1952, inclusive, 87 men and 129 women were treated for this condition. In 147 of these the poisoning was slight; the patients were not quite unconscious on admission, or they awoke soon afterwards. In 67, however, the poisoning was serious enough to put the treatment given to a severe test. The exact amount of the soporific each patient had taken per kilo body weight was not found to be as accurate a measure of severity as the duration of unconsciousness in the hospital. Another factor influencing the prognosis was the length of the interval between the taking of a soporific and admission to the hospital. The 67 severely poisoned patients were treated differently in the period 1947 to 1950 than in the period 1951 to 1952. In the first period, the stomach was washed out and charcoal and magnesium sulphate were introduced into it. Afterward stimulants were given in an attempt to awaken the patient. In the second period, attention was concentrated on keeping the respiratory passages open and combating shock. Endotracheal intubation and endobronchial aspiration were applied on the most severely poisoned patients and they were repeatedly shifted from one side to another and given oxygen through a fine rubber tube when necessary. Shock was combated by blood or plasma transfusion under close control of the pulse and blood pressure. Fluid balance was assured by the intravenous injection of glucose or physiological saline solution or a solution of sodium bicarbonate, and the urinary output was checked every hour with the help of a self-retaining catheter. Of the 38 patients treated in the first period, 15 of whom were unconscious for more than 24 hours after admission to the hospital, 9 died, and of the 29 treated in the second period, 14 of whom were unconscious for more than 24 hours after admission to the hospital, only 2 died.

CORRESPONDENCE

MIDDLE MENINGEAL BLEEDING

To the Editor:—The emergency existing in middle meningeal bleeding often places the general surgeon in a position of greatest opportunity to save these patients. Any reasonable suggestion for improving his management of patients with this highly fatal lesion should be heeded. The paper in the Dec. 19, 1953, issue of *THE JOURNAL* by R. B. Raney, A. A. Raney, and E. W. Peterson calls attention to the utility of ligation of the external carotid artery in halting bleeding from a lacerated middle meningeal vessel, but it seems incorrect to me to suggest that this procedure be done before the clot is evacuated.

The alarming rapidity with which patients with this lesion can progress from apparent normality to death has led to the realization that, once the lesion is considered probable, it is mandatory that some immediately available physician with sufficient boldness make a temporal opening and evacuate the clot without delay, and without regard for whether he has ever done the operation before. (It is not especially difficult.) It has been recognized that conditions do not need to be "ideal" for the satisfactory performance of this operation. *Indeed, it must be done, no matter what the conditions.* There is not often enough time remaining for these patients to await the arrival of a neurosurgical specialist or to permit transfer to a hospital better prepared for cranial surgery than the one in which the diagnosis is made. It does not seem wise to say, suggest, or imply that any other course of action is preferable.

In essence, the paper mentioned describes a single instance of a man who, some 12 to 18 hours after suffering a skull fracture with middle meningeal laceration, became comatose and cyanotic, with a dilated fixed pupil and medullary decompensation. The external carotid artery was ligated, after which the intracranial clot was evacuated. No particular intracranial bleeding of an active sort seems to have been encountered, but the patient was transferred to another hospital for reexpansion of the dura by saline solution and wound closure. It hardly seems justified to credit the favorable outcome for this patient to the preliminary ligation of the carotid artery. It must have taken just about as long to ligate the carotid as it would have taken to begin the evacuation of the clot, and, in the 20 to 30 minutes elapsing from the beginning of either procedure, the increase in clot volume would be identical. As carried out, with carotid ligation taking precedence over the clot evacuation, the patient suffered brain compression during the additional minutes necessary to do the cranial operation after the carotid was tied. The patient survived because the clot was evacuated in the remaining time this patient had to live. Evacuation of the clot was perhaps attended by less free bleeding than would have been the case had the carotid not been tied. To attribute more than this to the effect of the ligation seems unwarranted.

A statement is made in the first paragraph of this paper that ligation of the carotid "enables the patient to be maintained in status quo until adequate neurosurgical treatment can be instituted." This statement is not justified by any of the facts presented or marshaled in the report or by any others of which I am aware. The statement actually seems to encourage the general surgeon to choose the neck ligation over the less familiar temporal craniectomy, with the expectation that a living patient will be on hand some unspecified time later when a neurosurgeon is secured to evacuate the clot. Actually, a patient in a condition such as described in the case report cannot have long to live whether the carotid is tied or not, as long as the clot volume is undiminished. Later on in the paper, the statement is made that after the carotid is ligated, "severe cerebral compression may then be relieved

by a simple trephine opening and suction," but it is not emphasized that this should be done immediately (as the authors did) and not some hours later in another hospital.

It is my belief that no consideration should be given to carotid ligation as the initial procedure in cases of middle meningeal bleeding, if any means are available to perforate the temporal squama and if a surgeon of sufficient understanding and courage is available to make the perforation. No consequence of infection or bleeding can be more disastrous than the consequences of being 30 minutes too late with a middle meningeal hematoma. Carotid ligation is of definite value as a secondary operation, if the surgeon finds himself unable to locate the bleeding vessel or to control it with a ligature, unremoved hemostat, or packing before a neurosurgeon arrives to complete this technical detail. Carotid ligation deserves more notice, particularly to encourage the general surgeon who may hesitate to open the head for fear that he may be unable to stop the bleeding once he has done so.

USE OF FORCEPS

To the Editor:—The editorial on forceps on page 1450 of *THE JOURNAL*, Dec. 19, 1953, misses the most important statement in Jeffcoate's article, who, in turn, quoted Douglass and Kaltreider. There has been a tremendous effort by various committees, hospitals, and physicians to lower maternal mortality. Since *THE JOURNAL* has a wide circulation and since physicians will be influenced by the editorial, I am quite certain that they will attempt forceps and then perform a cesarean section, with a very definite increase in maternal mortality. Jeffcoate states trial forceps "could, of course, be abused and it has no place save in the hands of the expert working in hospital—the same qualifications which apply to the accepted practice of trial of labor." Douglass and Kaltreider state "It should be emphasized that trial forceps is a method of delivery which should be undertaken by a skilled obstetrician and not by the general practitioner who has had no specialty training." I feel that the competent obstetrician rarely needs to use trial forceps.

REMOVAL OF CERUMEN

To the Editor:—On numerous occasions, patients present themselves complaining of reduced or absent hearing, vertigo, tinnitus, headache, or otalgia. Examination of these patients is essentially normal, with the exception of the presence of impacted cerumen in the auditory canal. The symptoms are due to the impinging of the cerumen on the drumhead. Removal of the cerumen is followed by alleviation of the complaints. At times, removal of the impacted cerumen presents a rather difficult task. Irrigation and instrumentation proves painful and at times fruitless in attempting to loosen the inspissated and hardened cerumen. I have used a simplified method of removing the impacted cerumen and it has proved successful and of minimal discomfort to the patient. I introduce into the ear canal a weak solution of a commercial detergent (All or Drefit), and this is permitted to remain in the ear over night. The following morning the cerumen is very soft and very easily removed by gentle irrigation. Often the cerumen is spontaneously expressed, and the patient need not return.

COUNCIL ON MEDICAL SERVICE

This is the 12th in a series of studies made by the Committee on Indigent Care of the Council on Medical Service concerning local plans for medical care of the indigent. A general introduction to the series and the first of the Committee's studies (Erie County, New York) appeared in the May 10, 1952, issue of THE JOURNAL, pages 188-191. The 11th study (Vanderburgh County, Indiana) appeared in the Jan. 2, 1954, issue of THE JOURNAL, pages 83-84.

Medical Care for the Indigent in New York State

This is a study of medical services available to indigent and medically indigent residents of the state of New York. In 1950, the state had a population of 14,830,192, of whom 7,891,957 were residents of New York City. The state is highly industrialized and a wide variety of occupations are represented in its economy; agriculture employs a relatively small percentage of the state's population but is an important source of income in upstate New York.

ELIGIBLE POPULATION

Any person in the state who is demonstrably unable to meet the cost of needed medical services may obtain aid through his local welfare office. The comprehensive medical care program is, therefore, available to both those on assistance rolls and the medically indigent. Table 1 shows the number of clients receiving assistance from the various state programs during an average month.

TABLE 1.—Assistance Recipients, May, 1953

Program	New York City	Remainder of State	State Total
General assistance* (Home relief, veteran assistance)	56,020	19,070	75,090
Public assistance* (total).....	202,395	110,213	312,608†
Old age assistance.....	57,410	53,923	111,333
Aid to dependent children.....	119,586	45,126	164,712
Assistance to the blind.....	2,844	1,477	4,321
Aid to the disabled.....	22,555	9,687	32,242

* In New York, both local and federally aided programs are classified as "Public Assistance"; in this report, however, the term refers only to the four federally aided programs, in order to maintain uniformity with previous studies in this series.

† Includes 1,410 cases for hospitalization only; 2,635 for public home infirmary care only; 7,187 for hospitalization and assistance; and 811 for public home infirmary care and assistance.

ADMINISTRATION

New York's indigent care plan is administered at the local level with what is primarily supervisory activity at the state level. The general format was developed through the cooperation of the state welfare department, the state medical society, the local welfare authorities, and the local medical consultants; representatives of these groups continue to meet periodically as a joint committee to study and guide the program. The state's Department of Social Welfare is administered by a 15-member Board of Social Welfare appointed by the governor with the consent of the state senate. This board is chiefly a regulatory and advisory body; it establishes regulations for assistance administration, advises local welfare officers, approves or disapproves the various local welfare plans, administers those welfare programs for which the state alone is responsible, distributes financial reimbursement as prescribed by law, and regulates inspections of such institutions as hospitals and nursing homes. Local welfare districts that have not yet devised their own approved medical care plans operate and receive reimbursement under the state welfare department's general regulations, now in the process of revision. State supervision of these districts as well as of those that have plans is carried on through six area offices of the department. Much of the department's advice and guidance is provided by medical social workers from the headquarters and area offices who help local districts in evaluating social conditions, interpret medical policies, advise on difficult problems, and make continual studies of the medical welfare program with a view to improvements in care and administration.

Feeling that comprehensive medical service includes health promotion, disease prevention, and early detection of illness, treatment, and rehabilitation, state authorities have maintained a close liaison between the health and welfare departments. Since April, 1952, an assistant health commissioner has been assigned to head the Bureau of Medical Care of the Department of Social Welfare; he remains a member of the health department with access to its personnel, records, facilities, and guidance but is administratively responsible to the Commissioner of Social Welfare. This health officer develops the policies and procedures for the local welfare districts and assists them in developing their medical services; devises the standards by which the welfare department supervises and certifies hospitals, dispensaries, nursing homes, public homes, and private agencies; and coordinates state services to provide better care for the indigent. The Bureau of Medical Care, as an aid to local programs, allows the use of resources outside the particular district or outside the state to provide care when the individual case requires it and adequate local facilities are unavailable. The health officer also supervises the medical activities of the Commission for the Blind, the department's four training schools, the aged veterans' home, and the school for Indian children.

Legal responsibility for providing assistance to needy residents or transients is placed upon the 66 local public welfare districts. Eight of these are city districts (New York, Middletown, Oswego, Poughkeepsie, Auburn, Jamestown, Binghamton, and Newburgh), one is a town district, and the remaining 57 are county districts. County welfare districts may be administered on a county basis with service officers in the towns providing for emergency cases and giving information but with all other assistance applications forwarded to the county office; in the county-town system, town welfare officers can authorize and grant general assistance, including medical care, but public assistance applications must be referred to the county office. Cities included in county units may have the same type of administrative set-up as these towns. The welfare district is administered by a commissioner who determines the program of public assistance, including medical care, for his district, submits it to the state welfare department for approval, and is responsible for its operation once approved. The total assistance plan for a district must fulfill the following requirements: It must provide prompt access to benefits by applicants and recipients of assistance, standards of assistance and care, maintenance of adequate office facilities, and full-time service in those towns where home relief is a town charge. Needed services and assistance must be assured to those eligible without regard to the rate of reimbursement by the state, and the plan must include a description of the methods used in administering assistance in the district's towns and cities.

To achieve high quality medical care and a maximum of local autonomy in the medical part of these programs, five elements are considered essential: (1) definition and statement of scope of plan; (2) medical and social coordination; (3) medical and fiscal records; (4) integration with community medical and health resources, and (5) local medical direction and administration. Specific details vary from district to district, but, in general, the following methods are utilized to achieve these goals. A written statement is prepared by mutual agreement between welfare officers and medical personnel defining all phases of the medical program; medical needs are determined by physicians and the financial eligibility of applicants is determined by social workers, with joint planning when necessary. Complete records, both medical and financial, are kept for each patient as well as cost records by the type of service. The local welfare department keeps an inventory of all health facilities available for the community, whether federal, state, or local, so that all may be utilized; in establishing the program, the welfare commissioner meets with representatives of the medical and allied professions in the district and works out a plan to suit local conditions. When the plan has been approved by the state, a licensed physician is appointed as a medical consultant to direct the medical aspects of the plan, after consultation with the local medical society concerning his qualifications for the position. He establishes properly staffed central medical units to handle and refer all

requests for medical care. Through this close cooperation between local medical and welfare authorities, all available facilities are fully utilized, specific problems are equitably settled, and the program reflects and serves the needs of the particular community. (For a more detailed study of one of these local plans, consult the first report in this series, Erie County (Buffalo), New York, in the May 10, 1952, issue of *THE JOURNAL*, pages 188-191).

SERVICES AVAILABLE

The state Board of Social Welfare officially defines medical care for the indigent in the following terms: "... necessary preventive, diagnostic, corrective and curative service and supplies essential thereto, provided by qualified ... personnel ... for conditions ... that cause suffering, endanger life, result in illness or infirmity, interfere with his capacity for normal activities, or threaten some significant handicap." The local welfare districts, therefore, are required to provide a comprehensive program of medical services for assistance clients. Services generally available include physicians' care in home, office, and hospital by both general practitioners and specialists, all hospital services, nursing home and clinic services, home nursing and housekeeping services, ambulance service, laboratory facilities, drugs and appliances, eyeglasses, physiotherapy, and radium therapy. In general, it may be said that the indigent have available all medical services available in the welfare district. In most districts, the client has free choice of any physician in the community, although in two districts salaried physicians care for welfare cases. There are few limitations on service or on the professional personnel eligible to provide them; no limit is placed on hospital services, although all drugs must be prescribed by the attending physician.

PROVIDERS OF SERVICE

Any doctor of medicine or of osteopathy may participate in this program provided he is licensed by the state of New York to practice. Thus, with the exception of the two districts noted in which salaried physicians care for the indigent and a few in which the client must choose from a panel of co-operating physicians, there is almost unlimited freedom of choice of physician for the indigent patient. Specialist procedures may be undertaken by men recognized as specialists by their respective specialty boards or by physicians designated as specialists according to welfare department or workmen's compensation regulations. Any hospital may participate in the program if it meets the standards set by the American College of Surgeons and is certified periodically by the state welfare department; standards for participating nursing and convalescent homes have been established by the department. Any other professional personnel, including pharmacists and registered or practical nurses who are licensed by the state, may participate in the program; nursing care is provided by local private nurses, the Visiting Nurses' Association, and, in some cases, public health nurses. Thus, the indigent patient has available almost the entire range of medical personnel and facilities in the state, including some 459 hospitals, 88 dispensaries, 800 nursing homes, and 58 public homes certified by the welfare department.

PAYMENT FOR SERVICES

The state welfare department with the cooperation of the state medical society has devised a fee schedule for physicians' home and office calls and diagnostic and therapeutic procedures; if a local district pays the physician more than this schedule, the excess is not reimbursable from state funds. A general practitioner receives \$2.00 for office calls and \$3.00 for visits to the patient's home; nursing homes, boarding homes, private homes for the aged, and institutions for the blind. A specialist receives \$5.00 for initial calls, whether in his own office, the patient's home, or an institution; follow-up calls are \$3.00 at the physician's office and \$4.00 at the home or institution. General practitioners receive \$2.00 for hospital visits and specialists receive \$5.00 for initial hospital visits; however, if patients not on the assistance rolls receive free medical service at a particular hospital, no payment will be made to physicians for treatment of staff cases at that hos-

pital. For night calls \$1.00 is added to the fee and there is a mileage allowance of 35¢ per mile. Surgical procedures are reimbursed according to a correspondingly detailed fee schedule, which includes fees for surgical assistants.

Hospitals are reimbursed according to a flat per diem rate covering all hospital services. The method used to determine the maximum per diem rate was devised with the cooperation of the state hospital association and several agencies concerned with purchasing hospital care. Each hospital submits annual financial and statistical reports to the state welfare department. These figures are adjusted to eliminate items not directly related to inpatient care, such as depreciation on equipment and buildings; from the adjusted figures, each hospital's cost of operation per patient-day is calculated. When the hospital has ward beds only or private and semiprivate accommodations only, a further adjustment is made to approximate more closely the per diem cost of ward care. For the purpose of computing hospital rates, the state has been divided into regions, and hospitals in a given region are grouped by the number of beds—less than 50, 50 to 199, and 200 or more. Adjusted per diem costs for all hospitals of a given size in a region are averaged; per diem payment to an individual hospital may not exceed the average cost for its group by more than 10%. Laboratory services are reimbursed according to a detailed fee schedule as are prescriptions for eyeglasses. Payment for home nursing services is made according to local rates. Payment for drugs is made according to a formula based on the wholesale cost of drug and container: when this totals \$1.00 or less, the payment is the wholesale

TABLE 2.—1952 Assistance Costs

Program	Cost	Source of Funds		
		Federal	State	Local
General assistance (Home relief).....	\$ 41,304,940	\$.....	\$33,886,420	\$ 7,918,520
Public assistance.....	197,582,159	84,222,345	73,162,068	41,197,746
Old age assistance.....	91,732,076	40,022,082	31,898,960	19,811,034
Aid to dependent children.....	74,597,025	31,562,918	28,307,983	14,666,724
Assistance to blind.....	3,865,315	1,546,246	1,470,802	848,267
Aid to disabled.....	27,387,143	11,091,099	10,424,323	5,871,721
Totals.....	\$238,887,099	\$84,222,345	\$105,548,488	\$49,116,266

cost plus $\frac{2}{3}$ with a 50¢ minimum; when this is over \$1.00, the payment is the wholesale cost plus $\frac{1}{2}$. Payment for compounded prescriptions is based on a comprehensive fee schedule, and "over the counter" drugs are reimbursable at retail prices. Sick room supplies are reimbursed at cost plus 50%.

COSTS AND FINANCIAL SUPPORT

Under a new welfare formula, inaugurated Jan. 1, 1954, the state shares in the cost of all welfare programs authorized by the state social welfare laws; federal aid grants for public assistance are allocated to the local districts and all remaining costs of authorized welfare programs are shared equally by state and locality. This provides state support for the care of the following groups, previously local charges only: wards of city or county welfare departments, indigents in public homes, public home infirmaries, and municipal lodging houses and shelters, hospitalized home relief clients, and children under foster care. The previous formula called for 80% underwriting of costs by the state for the home relief program; the new rate of contribution is 50%. However, the state will pay 80% of costs for the number of home relief clients in excess of 1% of the district's population, if these clients should exceed this number. The formula for support of the state tuberculosis program has also been revised, and state support for the medical care involved has been increased.

The following table shows the expenditure for each of the assistance programs during 1952 and the source of the funds utilized.

The amount of assistance expenditures in New York reached a peak in 1950 and decreased slightly in 1951 and 1952; however, the percent of total assistance costs and the amount expended for medical services have increased steadily since

1947. In that year, about seven million dollars were spent on medical services, approximately 4.2% of total costs; in 1952, medical costs reached 23.5 million dollars, 10.1% of the total. About two-thirds of the medical expenditures annually are for hospital services, while the remaining one-third provides professional services, drugs, and other medical items. In 1952, approximately \$40.21 was spent for hospital services per eligible assistance client and \$20.47 for other medical services.

MEDICAL SOCIETY RELATIONSHIP

The Medical Society of the State of New York has appointed a special liaison committee to meet with the state welfare department; the committee assists in improving medical care for welfare clients and interprets the welfare policies to the medical profession. The total program has had the aid and cooperation of the medical society, both in devising the most efficient methods of utilizing medical personnel and facilities and in obtaining the support of the individual physician. The degree of participation by local county medical societies, of course, varies from district to district. The most successful programs seem to be those in which county societies have become interested and active participants. The fact that medical care provided in these local programs must be under the supervision of a physician in itself fosters cooperation with local medical societies. Some societies have established medical care advisory committees that work with the welfare department and the medical supervisor, advising on specific problems, the formulation of medical care policy, and the utilization of all local health facilities, and interpreting the program to the society members. Such committees frequently also serve to review complaints and control abuses of the program. In general, the medical societies seem to be active and interested participants in the indigent care programs throughout the state.

SUMMARY

The New York state indigent care program is locally administered through city, county, and town welfare districts; each district devises its own plan of care and the state welfare department acts primarily in a supervisory capacity. All plans, however, must meet certain requirements of the state welfare authorities so that, in general, the plans provide approximately the same benefits. All assistance clients are eligible for the same medical services, and medically indigent citizens of a welfare district are eligible for the same benefits as those on the assistance rolls. Since the plans attempt to utilize all suitable medical facilities and personnel in the district, it may be said that welfare clients have available the same type of medical care as nonindigent residents of the community. Two districts employ salaried physicians to care for the welfare clients and several have panels of participating physicians; aside from these, however, most plans allow the client complete freedom of choice of physician. Any facility may be used that meets the standards of the state welfare department and every medical service will be provided that the physician deems medically necessary; the plans utilize general practitioners and specialists and provide care in the patient's home, the doctor's office, the hospital, and in clinics, nursing homes, and convalescent homes. Home nursing is provided when necessary. Physicians are ordinarily paid according to detailed fee schedules, state reimbursement to local districts being based on a state-wide schedule established in cooperation with the state medical association. Hospitals are paid a flat rate per diem covering all services, which is based on the cost of actual operation of the individual hospital and of other hospitals of the same size located in the same region of the state. Beginning Jan. 1, 1954, the state will share in the costs of all welfare programs authorized by the state's social welfare laws, including local general assistance programs.

The administrative structure permits maintenance of uniform standards of eligibility and services yet leaves local organization flexible so that the district may devise a plan to meet its own individual needs and to make full use of its own medical facilities. The plan seems effective in providing good medical care, suited to local conditions, with a minimum of governmental "red tape."

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Naturopathy: Naturopaths Required to Be Licensed Even in Absence of Separate Licensing Act.—This was a declaratory judgment action to determine the rights of the plaintiffs to practice naturopathy without first securing a license from either the board of medical examiners, the board of osteopathic examiners, or the board of chiropractic examiners. From a judgment in favor of the defendants, the plaintiffs appealed to the district court of appeal, second district, division 3, California.

The plaintiffs, graduate naturopaths and chiropractors, asserted that the practice of naturopathy is beneficial and not harmful, that naturopaths cannot obtain a license in California under existing laws, but that naturopaths are nevertheless subject to prosecution if they practice without a license. They therefore contended that naturopaths are the subject of unjust and unconstitutional discrimination. The defendants are the boards of medical examiners, osteopathic examiners, and chiropractic examiners. They contended that naturopaths can be licensed by either the medical, osteopathic, or chiropractic boards and that licentiates of such boards are permitted to employ naturopathic methods in their practices if they desire to do so. Thus, they argued, naturopathy is regulated, not prohibited.

The court admitted that there is no law in California under which plaintiffs may be licensed as naturopaths. The Business and Professions Code, however, provides: "Any person who practices or attempts to practice, or who advertises or holds himself out as practicing, any system or mode of treating the sick or afflicted in this state, or who diagnoses, treats, operates for, or prescribes for any ailment, blemish, deformity, disease, disfigurement, disorder, injury, or other mental or physical condition of any person, without having at the time of so doing a valid unrevoked certificate as provided in this chapter, is guilty of a misdemeanor." The use of natural methods of healing is not forbidden by law. Physicians and surgeons, osteopaths, chiropractors, and all those who hold licenses as drugless practitioners may use them. It is of common knowledge that nature is the indispensable healing agency and that practitioners of medicine and surgery, osteopathy, and chiropractic make use of the curative qualities of light, air, water, rest, diet, and physical and mental culture, in connection with the agencies peculiar to their several systems of healing. The several medical practice acts have never had application to treatment by prayer or the practice of religion, but with this exception they have forbidden the practice of any of the healing arts by those who were unlicensed. Plaintiffs, being unlicensed, may not under the present law practice at all. They must become licensed either as physicians and surgeons (which now includes osteopaths) or as chiropractors in order to employ their methods, although even then they cannot practice naturopathy in its true sense, inasmuch as they cannot use the title "naturopath" or "N.D." nor hold themselves out as such. We do not discover in this situation a sound basis for the claim of unreasonable discrimination with respect to these plaintiffs, said the court.

The Business and Professions Code provides "Nothing in this chapter shall be construed so as to discriminate against any particular school of medicine or surgery, or any other treatment." This provision against discrimination, said the court, has been the law, substantially in its present form, since 1907. It applies primarily to administration of the act. No illegal discrimination against naturopaths has been shown.

Accordingly the judgment of the trial court finding that the plaintiffs were required to be licensed by either the board of medical examiners, the board of osteopathic examiners, or the board of chiropractic examiners was affirmed. *Oosterveen v. Board of Medical Examiners*, 246 P. (2d) 136 (California, 1952).

Interstitial Fibrosis of Lungs.—The literature relevant to diffuse bilateral interstitial fibrosis of the lungs is reviewed, and three new cases are reported. The disease is one of adult life; its etiology is unknown. It develops progressively, with long duration of symptoms. These include dyspnea, cyanosis, and cough, accompanied by a latent tendency toward the development of cor pulmonale and polycythemia. Pathologically, the condition is characterized by diffuse alveolar wall hypertrophy on the basis of marked capillary proliferation. This hyperplasia is limited to the alveolar walls and accounts for their thickness. The addition of collagen in such walls is variable; it may be absent and is usually focal rather than widespread. The disease originally designated as acute interstitial fibrosis of the lungs proves to be progressive diffuse alveolar hypertrophy of a specific reticuloangiomatic type.

Phenylbutazone.—Phenylbutazone (Butazolidin) was administered to 800 patients with various diseases during the period August, 1951-April, 1953. This report deals with phenylbutazone used alone. (It was formerly used as Butapyrin, a combination of equal parts of aminopyrine and phenylbutazone.) The clinical usefulness of phenylbutazone was evaluated by relating therapeutic response to toxicity. On this basis, it was found to be much more useful in gout than in any other disease in which it was studied. The authors' opinion is that it is the drug of choice in the treatment of this disease. Phenylbutazone also was clinically useful to a lesser extent in psoriasis with arthritis, ankylosing spondylitis, rheumatoid arthritis, and painful shoulder. Its use in malum coxae senilis, osteoarthritis, osteoporosis, and mixed arthritis is limited by a greater incidence of toxicity without a commensurate degree of clinical improvement. Among the 800 patients, 321 (40%) exhibited 457 untoward side-effects. It was necessary to discontinue medication because of toxicity in 121 patients (15%). The most frequently encountered reactions included water retention,

nausea, rash, epigastric pain, vertigo, and stomatitis. Unusual severe reactions included peptic ulcer activation (1%) with bleeding in three patients (0.37%), hepatitis (0.25%), agranulocytosis (0.6%), thrombocytopenia (0.12%), and purpura without thrombocytopenia (0.5%). Toxic side-effects were seen more frequently in women than in men.

Hepatitis and Pooled Plasma.—A study of the incidence of hepatitis was made in 587 patients who were wounded in Korea. Of these, 255 received transfusions of blood and plasma and 332, of blood alone. The incidence of hepatitis with jaundice in the first group was 56 (21.9%) as compared with 12 (3.6%) in the second. The mean incubation period of the hepatitis in these 68 patients was 90.3 ± 11.7 days. This is presumed to indicate that the disease involved was long-incubation-period hepatitis (serum hepatitis) and not short-incubation-period hepatitis (epidemic hepatitis). Some of the blood and plasma used in the transfusions had been specially treated for the hepatitis virus by irradiation with ultraviolet light; but comparative results of treatment with both types of material showed no significant capacity of the irradiated material to prevent the occurrence of hepatitis.

Morphology of Kidney in Morbus Caeruleus.—Meessen and Litton apply the term morbus caeruleus to the group of congenital heart lesions with cyanosis and persisting venous-arterial shunt. The reduction in oxygen tension and the presence of reduced hemoglobin are responsible for the cyanosis. Fallot's tetralogy with its variations is found in most of these patients. The authors examined the kidneys of patients with morbus caeruleus for morphological changes resulting from the chronic hypoxia; 28 kidneys were studied. Capillary loop ectasia with resulting glomerular enlargement is characteristic of the morbus caeruleus kidney. Vasa afferentia are widened, and the draining veins are dilated. Fibrous obliteration of glomeruli, partial obliteration of capillary loops, and widening of the interstitial tissue were also observed. The chronic hypoxia of morbus caeruleus did not result in the destruction of kidney parenchyma. The authors believe that in the renal changes they observed the chronic hypoxia and the increase of carbon dioxide are the chief factors. Consequent dilation of the glomerular arterioles and widening of the vasa afferentia facilitate the glomerular circulation. The adaptation to the chronic hypoxia is accomplished by capillary loop ectasia, which results in glomerular enlargement. These local tissue adaptations in the kidney and the developing polycythemia fully compensate for the chronic hypoxia. Thus no damage due to oxygen deficiency results. The tubular epithelium was always intact. The authors

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

recall that Scott and Elliot investigated the effects of anoxemia and polycythemia on renal hemodynamics and excretory functions in 19 patients with congenital malformations of the heart and cyanosis. These investigators found that the glomerular filtration rates were normal despite depressed renal plasma flow. The renal blood flows were above normal in most of the patients. Meessen and Litton believe that the clinical observations of Scott and Elliot are in keeping with their own observation of glomerular enlargement and resulting increase of available surface for filtration. The widening of the vasa afferentia would also facilitate the glomerular circulation. They found no specific anatomic evidence to support an increase in postglomerular resistance assumed by Scott and Elliot.

Variations in Tetralogy of Fallot.—Of 350 postmortem specimens of congenital malformations of the heart at the Children's Memorial Hospital in Chicago, 42 fulfilled the criteria for tetralogy of Fallot and were evaluated with respect to the relative applicability of intracardiac infundibular resection and the shunt operations. Twelve specimens with atresia of the pulmonary valve, the infundibulum, or the entire main pulmonary artery were not studied extensively because at the present time there is agreement that a systemic pulmonary shunt is the only possible procedure in this type of malformation; 4 of the 12 had an adequate pulmonary arterial segment to permit such a shunt operation. The remaining 30 hearts had patent pulmonary arteries associated with stenosis of the infundibulum, and either pulmonary valvulotomy or systemic pulmonary anastomosis would have had to be considered in these hearts; they were studied extensively and divided into five groups, each of which consisted of a variable number of hearts with relatively similar infundibular pathology. Eight specimens (19%) belonged to the group with "band stenosis" in which a thin fibromuscular band at the ostium of the infundibulum associated with a dilated infundibular chamber above the point of obstruction made intracardiac resection of the infundibular stenosis feasible. The hearts in this group were taken from older patients and had the least severe degree of overriding. The remaining 22 hearts belonged to the four other groups and were probably not amenable to intracardiac surgery at this time. Ten, or one-third, of the 30 hearts with patent pulmonary arteries had valvular stenosis accompanied by infundibular deformity in all and associated hypoplastic pulmonary arteries in 8. Most specimens had moderate or severe overriding of the aorta. Thirty-four (82%) of the 42 hearts were taken from children less than three years of age. These specimens probably represented more severe types of tetralogy of Fallot. Studies made by other workers with findings different from those of the authors, were done mainly on older children and adults. The difference in ages may account, in part, for the difference in pathological observations.

Alseroxylon-Hexamethonium for Hypertension.—Alseroxylon (Rauwiloid), an extract of *Rauwolfia serpentina*, was used in combination with hexamethonium for the treatment of 25 patients between the ages of 32 and 71 with essential hypertension. Nineteen of the patients were first given hexamethonium orally starting with small doses of 250 mg. four times per day and then progressively increasing the dose in an incremental fashion until an optimal response was obtained. Most of these patients were observed for six months or longer before the addition of alseroxylon. When alseroxylon was added, it was also started in small doses, 2 mg. four times per day, and the dose was progressively increased by increments. The dose was maintained at 32 mg. daily in most patients, although current data seem to indicate that 8 to 12 mg. (4 to 6 tablets) per day is adequate and that little additional hypotensive effect may be produced by the larger dose. Alseroxylon was used as the initial drug in six patients, and a period of at least three months elapsed before hexamethonium was added to the therapeutic regimen, thus allowing to evaluate the hypotensive response to alseroxylon alone. The drugs were taken four times daily, with meals and at bedtime. In the six patients to whom alseroxylon was administered initially, there was a decrease in the average mean blood pressure (diastolic plus one-third of the pulse pressure) from 159 (208/134) to 137 (183/113) mm. Hg, but after hexamethonium was added there was a much greater reduction, namely, to 104 (147/83) mm. Hg. In the 19 patients in whom therapy was initiated with hexamethonium, there was an average reduction in mean blood pressure from 150 (199/125) to 104 (136/88) mm. Hg; another slight drop to 97 (127/83) occurred when alseroxylon was added. There was also a decrease in pulse rate after adding alseroxylon that was not observed when hexamethonium was given alone. Twenty (80%) of the 25 patients treated became normotensive during combined alseroxylon-hexamethonium therapy; and 25 (100%) had a decrease in mean blood pressure of at least 20 mm. Hg. There was also a reduction in the frequency and severity of the unpleasant side-reactions that were previously observed when hexamethonium was used alone, and the beneficial side-effects of alseroxylon, such as increased appetite and sedation without somnolence, persisted. The dose of hexamethonium could be reduced on combined therapy with alseroxylon, and the blood pressure was reduced further and was better stabilized. Alseroxylon could be used initially in most patients with severe essential hypertension; those not responding in six to eight weeks should also be given hexamethonium.

Erythromycin and Penicillin in Pneumococcal Lobar Pneumonia.—Of 50 patients with pneumococcal lobar pneumonia, 24 were given erythromycin (Ilotycin) and 26 received penicillin. Erythromycin was administered orally in doses of 400 mg. on

admission and 400 mg. every six hours thereafter for 72 hours. Penicillin was administered intramuscularly in doses of 300,000 units of the aqueous sodium salt on admission and every 12 hours thereafter for 72 hours. The infections were considered to be of comparable severity in both groups except for the higher incidence of bacteremia among the patients treated with erythromycin. There were three deaths; one of the two patients treated with erythromycin who died was in shock and was given penicillin concomitantly; the third patient received penicillin alone. Complications occurred with equal frequency in both groups. No untoward reactions were noted that could be ascribed with certainty to either chemotherapeutic agent. Erythromycin did not give rise to gastrointestinal symptoms. Thus results obtained with the two antibacterial agents were similar and suggest that erythromycin is a suitable drug for the treatment of pneumococcal lobar pneumonia. Limitations of erythromycin are: it exerts antibacterial activity against only a limited number of bacterial species; a clinically significant degree of resistance to erythromycin may develop *in vitro*; its relative insolubility and the unavailability of a preparation for parenteral administration that may be required in critically ill patients. Erythromycin may be reserved as an alternative form of treatment in pneumococcal lobar pneumonia, its principal value being in the fact that it may be administered to patients previously sensitized to penicillin.

New Approach to Treatment of Brucellosis.—Of 139 patients with brucellosis caused by *Brucella mellitensis*, 44 with duration of the disease from 8 days to two years and 24 with duration of the disease from 15 days to 8 months were treated with subcutaneous injections of amphoteric oxytetracycline (Terramycin) in amounts not larger than 160 mg. per week. The remaining 71 patients were divided in two groups of 44 and 27 patients with similar duration of the disease and served as controls. The course of the bacteremia was considered the only reliable criterion for the evaluation of the results. While the course of bacteremia was uninterrupted for a period of two to three months in the control patients, positive blood cultures were obtained from only 18% of the treated patients 15 days after the beginning of treatment, and subsequent cultures became negative. The uniformity of the results left no doubt that this striking difference in the course of bacteremia in the treated and in the control patients was due to the small doses of precipitated oxytetracycline injected into the thick subcutaneous layers of the gluteal region. Treatment of brucellosis with relatively insoluble particles of oxytetracycline was based on the concept that because of the physicochemical properties of oxytetracycline a minor fraction of the absorbed or injected drug might precipitate in the plasma due to its low solubility in neutral reaction; the precipitated particles might be phagocytized and eventually reach the lymph nodes, the spleen, and other organs. Since reticuloendothelial cells are considered choice hosts of *Brucella*, there would be a possibility that particles of the antibiotic might come in contact with the parasite either by direct phagocytosis or phagocytosis of leukocytes carrying these particles. The results obtained in the authors' patients seem to support this hypothesis.

Selective Pituitary Failure.—The term selective pituitary failure is suggested by Maddock and associates for the lack of secretion of one or more, but not all, anterior pituitary tropic hormones, as contrasted with panhypopituitarism in which there is uniform depression in the secretion of all pituitary tropic hormones. The authors describe a type of selective pituitary failure observed in four men between the ages of 38 and 58 in whom failure of gonadotropin and adrenocorticotropin secretion was associated with evidence of intact thyrotropin secretion. Deficient gonadotropin secretion was manifested by clinical evidence of pronounced hypogonadism, biopsy evidence of testicular atrophy, and laboratory evidence of low urinary gonadotropin excretion. Deficient corticotropin secretion was demonstrated by clinical and laboratory evidence of adrenal cortical insufficiency that responded in an initially delayed but eventually satisfactory manner to treatment with corticotropin (ACTH). Adequate thyrotropin secretion was manifested by clinical and laboratory evidence of normal thyroid function. The duration of the disease varied from 6 to 24 years, yet each

patient responded adequately to the administration of corticotropin. Irreversible testicular damage, however, prevented a response to large doses of chorionic gonadotropin (2,000 to 5,000 units given intramuscularly daily for 48 days) necessitating substitution therapy with testosterone propionate (25 mg. intramuscularly daily). It can be expected that although corticotropin given initially in daily doses of 25 to 50 units in aqueous vehicles intramuscularly and in daily doses of 10 units in either aqueous or long-acting vehicles for maintenance treatment will correct the adrenal cortical deficiency, testosterone propionate substitution therapy, rather than stimulation with gonadotropins, will be necessary to correct the androgen deficiency in most long-standing cases of hypopituitarism.

Bronchogenic Cysts.—The occurrence of ectopic teratism is reported in four men between the ages of 22 and 29 and in five infants, three boys and two girls. In several of these nine patients gross anatomic defects were recognized clinically as well as roentgenographically, but the etiological nature of the deformity was not suspected prior to either operative intervention or postmortem examination. Of the four adult patients, one had a bronchogenic cyst intimately attached to the superior vena cava, one a large bronchogenic cyst occupying the posterior mediastinum and obliterating the right border of the heart, one a bronchogenic cyst communicating with the right stem bronchus through a small caliber rudimentary bronchus indicated by an air-fluid level, and one an intramural, submucosal type of defect in the distal end of the esophagus produced by an embedded bronchogenic cyst. Of the five infants, one had a large paratracheal bronchogenic cyst, one a thymoma extending into the upper right chest cavity that roentgenographically could not be differentiated from a cyst, one a cyst impregnated with calcium salts that had inspissated a small

duplication of the upper jejunum, one an upper extrinsic pressure defect produced by a duplicate stomach and a lower defect produced by an abdominal bronchogenic cyst, and one a bronchogenic cyst in the infraclavicular region on the anterior chest wall. Since the roentgen signs for accurately establishing the diagnosis of "cyst" are meager, the type of cyst (uncomplicated) can be determined only by histopathological study of its wall or indirectly through examination of its contents. In adults the differentiation of cysts from malignant or potentially malignant tumors is so difficult that excision is both desirable and advisable. In infants and children, gastric cysts, if at all productive of symptoms, are usually rather rapidly fatal unless removed. The diagnosis of the type of cyst is scarcely necessary since almost all cysts of the mediastinum may give rise to fatal complications and should therefore be removed surgically unless there is a serious contraindication.

Tricuspid Insufficiency.—Insufficiency of the tricuspid valve was demonstrated by angiocardigraphy and cardiac catheterization in 12 patients, in 6 of whom a clinical diagnosis of tricuspid insufficiency had been made. All of these patients had chronic rheumatic mitral stenosis, all had auricular fibrillation and several were studied preliminary to surgical intervention on the mitral valve. Tricuspid insufficiency is commonly associated with mitral stenosis of a degree sufficient to warrant consideration of mitral commissurotomy, and it is not necessarily regarded as a contraindication to this operation. Cardiac catheterization offers the most accurate means of establishing the diagnosis. Angiocardigraphy with sodium acetrizoate (Urokon Sodium 70%) as the preferred contrast medium, reveals dilatation of the superior vena cava and the right atrium and occasionally demonstrates a filling defect in films exposed during early opacification of the right atrium. This is due to regurgitation of nonopacified right ventricular blood through the incompetent tricuspid valve. Multiple exposure studies facilitate the differentiation of this finding from changes that are the result of tumor or thrombus within the right atrium.

Gas in Intervertebral Disks.—The so-called vacuum phenomenon in intervertebral disks was recognized only in recent years, and few cases were reported in the literature. It is shown roentgenographically as an area of decreased density in degenerating disks, and Marr suggests that these areas of decreased density contain gas from surrounding fluids that have been vaporized as the result of a partial vacuum. Of 2,419 men between the ages of 19 and 72 subjected to x-ray examination of the lumbosacral spine, 49 (2.026%) had gas in at least one disk in this area; 10 of these patients had gas in more than one of these disks, so that a total of 61 disks were involved. The lower two disks comprised 44 (72.1%) of the 61 involved disks; the high incidence of gas in the lower lumbosacral area is probably due to greater stress on these two disks. The average age of patients who had gas in disks was 57; the youngest patient was 49. Narrowing of the spaces between the vertebral bodies, spurring of adjacent margins, and eburnation of adjacent bodies were other changes frequently associated with gas in disks. Further studies are needed to provide more information about gas in disks, a phenomenon that may be frequently overlooked.

Electrosurgery in Cutaneous Neoplasms.—Cipollaro attempts to refute what he believes to be faulty criticism of electrosurgery. It is true that wounds following electrosurgical procedures require a longer healing time than noninfected wounds produced with a sterile scalpel that heal by primary union. However, in treating lesions about the eyelids, ears, and nose, the

cosmetic result following electrosurgery is usually superior to that following scalpel surgery. Electrosurgical technique often obviates hospitalization and the expenditures for the use of the operating room and the anesthetist's fee. The statement that the use of electrosurgery for the treatment of a benign tumor causes it to become malignant should not be taken seriously. Electrosurgical currents are adequate, safe, and efficient for the treatment of most benign and malignant tumors of the skin. Electrodesiccation is employed far more frequently than electrocutting or electrocoagulation, and, therefore, a "spark gap" high frequency apparatus is more desirable than a "tube" machine. Local procaine anesthesia is usually employed. The use of the curet is an essential part of the procedure of destroying cutaneous lesions with electrosurgery. Basic rules of surgical procedures and of antisepsis must be adhered to for successful results. The following tumors lend themselves to treatment with electrosurgery; adenoma sebaceum, angioma, cutaneous horn, dermatofibrosarcoma protuberans, epithelioma, fibroma, fibrosarcoma, granuloma pyogenicum, Kaposi's sarcoma, keloid, keratoses, lipoma, melanoma, myoblastoma, nevi, rhinophyma, verrucae, xanthoma, and xeroderma pigmentosum. Some of these tumors may also be treated with other methods.

Maldevelopment of Corium in Osteogenesis Imperfecta.—Follis recently called attention to certain hitherto unreported morphological alterations in the skin, eye, and skeletal tissues of an infant coming to autopsy with the classic manifestations of osteogenesis imperfecta congenita. In the skin, the primary change appeared to be a failure of the normal transformation of reticulum fibrils into mature, nonargyrophilic collagen fibers. Since this abnormality had not been described before, dermal tissues of subsequent cases of osteogenesis imperfecta were examined with great interest. This report presents observations on the skin from four additional cases that have become available for study since the previous communication. In all, particularly those in which the skeletal tissues were most affected, the corium showed a characteristic abnormality, namely failure of argyrophilic reticulum fibrils to be transformed into adult argyrophilic collagen fibers.

Histamine of No Benefit in Multiple Sclerosis.—This study was undertaken as a direct result of the unusual public interest aroused by reports in the lay press regarding histamine in the treatment of multiple sclerosis. Histamine was administered intravenously or by iontophoresis to 19 patients with clearly established diagnoses of multiple sclerosis. In

each of the three classifications of the disease (stationary, progressive, and acute), no significant difference in improvement between treated and control groups was observed. Control cases were those in which treatment was identical except for histamine therapy. In four of seven cases of progressive disease further deterioration occurred despite histamine therapy. Of the other three patients, one died a year later and another returned to the hospital in three months with severe symptoms that were not relieved with further histamine treatment. In two patients with remittent disease new symptoms, presumably caused by new lesions of the central nervous system, developed while histamine therapy was in progress. In cases of stationary disease histamine treatment was of no benefit.

Platelet Thrombosis Syndrome.—The clinical and necropsy findings in seven cases of platelet thrombosis syndrome support the belief that vascular damage precedes the formation of thrombi. Search for prethrombotic vascular changes led to their discovery in several instances. The average duration of the illness was 17 weeks; in one case it lasted for the unusually long period of nine months. Fever of from 99 to 102 F was a constant feature. Hemorrhagic manifestations, consisting of purpura, retinal hemorrhages, hematuria, or bleeding gums or epistaxis, were noted in five cases. Pallor, weakness, and easy fatigability were notable in five patients in whom anemia was severe, and in four of these jaundice was also present. Anemia in the other two patients was minimal. Neurological disturbances, shown by six patients, included headache, drowsiness, mental confusion, convulsions, focal paresthesia, and paresis. Anisocytosis, poikilocytosis, reticulocytosis, and nucleated red blood cells were frequently present. Platelet counts in one case were repeatedly within normal range with an unexpected transient prolongation of prothrombin times. The most characteristic necropsy finding was the widespread presence of hyaline thrombi in the small arteries, arterioles, and capillaries. These platelet thrombi were present in the kidneys and myocardium in all cases. The major organs least frequently involved were the lungs and liver. The bone marrow was uniformly hyperplastic. The possibility that the syndrome may be secondary to a variety of underlying conditions is suggested by the

fact that associated processes capable of causing vascular damage were noted in four of the seven patients, one of whom had glomerulonephritis, one lead poisoning, and two malignant hypertension.

Control of Hypertension by Hyphex.—The term hyphex, formed from the words hydrazinophthalazine and hexamethonium, is used to designate a new and effective method of controlling arterial hypertension. The simultaneous administration of hexamethonium chloride and hydrazinophthalazine (hydralazine) according to a carefully determined schedule varying with the response in each case results in sustained lowering of the elevated blood pressure. No adequately managed patient failed to respond to the treatment, but modifications of the schedule resulted in failure. Substitution of placebos for one of the drugs was invariably followed by a progressive rise in blood pressure. Patients in malignant stages sometimes died within from two to four days after discontinuing the treatment. The method has been used for from 6 to 25 months in 258 patients, of whom 89 were in malignant, 5 in terminal uremic, and 130 in severe benign stages of hypertension. The blood pressure fell in all cases and was maintained at reasonable levels in approximately 80%. Tolerance did not develop when the method was strictly followed. The malignant stage was altered in all cases, but only three-fourths of the patients survived. Renal insufficiency is in many cases a limiting factor in the effectiveness of hyphex. The method is not ideal, but even in these initial trials it has been shown that control of hypertension is both practical and feasible for patients who are willing to cooperate, if certain precautions are taken to prevent hypotension and obstipation. The present report, which deals with the effect of hyphex on the blood pressure, will be followed by others dealing with special problems.

Direct Surgery in Arteriosclerosis.—The factors responsible for success or failure in the surgical treatment of arteriosclerotic segmental obstruction in the peripheral arteries may be grouped under two headings: (1) proper selection of patients and (2) technical details of surgery. Resection and replacement of an obstructed segment was accomplished in 30 patients (bilaterally in 1); of these grafts, 16 were successful and 15 failed. The results obtained in this series, small though it is, show that there are certain definite indications and contraindications for surgical treatment of this condition. One finding common to all candidates for superficial femoral artery resection is the presence of a femoral pulse and the absence of one at the popliteal level. This does not necessarily mean that the obstruction is limited to the superficial femoral artery, but it does provide a broad basis for selection. Claudication is the symptom that prompts these patients to seek medical attention, and the likelihood of success is diminished if other symptoms are present. Age does not seem to be an important factor in the outcome; the average age of the patients in whom the grafts were successful was 52, and that of those in whom they failed was 51. Rest pain and trophic changes in the foot of the affected extremity are the outstanding contraindications. None of the patients in whom the grafts were successful presented these symptoms, but they were found in several of the patients in whom the grafts failed. Arteriography, though sometimes misleading, is an essential aid in the correct selection of patients for femoral grafting. Injury to collateral vessels should be carefully avoided, because the existence of such vessels may mean the difference between maintenance of the preoperative state or its deterioration if the graft fails. Femoral vein autografts were used with success in two patients, both of whom are symptom-free after periods of 23 and 22 months respectively. Saphenous autografts were used in 22 patients with 13 failures and 9 successes. Saphenous homografts succeeded in four of six cases, and one such graft, listed as a failure, was never implanted because of the friability of the host's vessels. The blocked segment of the femoral artery may be either removed or left in place as indicated by the circumstances in each case. Anticoagulants apparently were not an important factor in the success or failure of the grafts.

Persistence of Left Superior Vena Cava.—Persistence of a left superior vena cava, a congenital anomaly of considerable interest, was detected during life by angiocardiography and cardiac catheterization in five women between the ages of 21 and 49, one 21-year-old man, and three boys and two girls between the ages of 3 and 6. It occurred as an isolated lesion in three women and was associated with other congenital cardiac anomalies, such as situs inversus, dextrocardia, interatrial and intraventricular septal defects, tricuspid atresia, tetralogy of Fallot, and infundibular pulmonary stenosis, in all the children and in the other two women. Persistent left superior vena cava without a right superior vena cava but in the absence of any other cardiovascular abnormalities was observed in the man. Persistent left superior vena cava is a relatively simple defect of development that as a single lesion produces no detectable adverse effects on the function of the heart aside from the fact that it may occasionally simulate widening of the aorta during roentgenography of the heart. The association of persistence of left superior vena cava with complex cyanotic types of congenital cardiovascular disease is, however, noteworthy. Although a left superior vena cava may be suspected on fluoroscopy, it can be positively identified in the living patient only by angiocardiography or cardiac catheterization. A left superior vena cava may be missed during angiocardiography unless the left arm veins are used for the injection of contrast mediums. Even though 11 cases were observed by the authors, many more were probably missed because injection of the right arm for angiocardiography is preferred since this simplifies positioning of the patient for left oblique and lateral studies of the heart. Catheterization of the heart through the left arm veins, routinely used by the authors, affords the opportunity of entering a left superior vena cava. In some of their cases demonstration of the left superior vena cava could be accomplished

by catheterization of the right superior vena cava, passing the catheter through the right superior vena cava, the right atrium, into the coronary sinus, and up the left superior vena cava.

Fibroanthracosis of the Lungs.—Of 770 necropsies performed on indigent residents of Pittsburgh who died at the average age of 60, with men predominating in a ratio of 3 to 1, 97 showed some degree of fibroanthracosis, an incidence of 12.5%. In 8 of the 97, fibroanthracosis was listed as the principal cause of death, a fatal incidence of 1%. In two additional cases fibroanthracosis was a contributory cause of death in patients with pulmonary tuberculosis. These 10 patients were men, and 6 of them had been coal miners for 4 to 33 years. Analysis of the causes of death in the 97 cases of fibroanthracosis indicated that its presence in the lungs did not increase the incidence of or predispose to death from other lung diseases such as pneumonia, tuberculosis and bronchogenic carcinoma. Fibroanthracosis was observed in only seven women, and in each of these lung damage was slight and had no effect on the patient's death. Most of the fatal cases of fibroanthracosis occurred in coal miners. The mechanism of death was congestive heart failure. Right ventricular hypertrophy was pronounced in almost all of the fatal cases. These results suggest that long-continued exposure to a smoky atmosphere such as that of the Pittsburgh district in which coal mining is a large, essential industry, while it may cause minimal scarring after many years, does not result in any appreciable degree of lung fibrosis. Fibroanthracosis of the lungs, in this district at least, is an occupational disease, predominantly if not entirely associated with coal mining.

Metastases to Bone from Bladder Tumors.—Kinne presents the case of a man, aged 49, who was first seen in July, 1949, complaining of painless hematuria that had existed over the past year and had been constant for the past

three months. Cystoscopy revealed an irritable bladder and a large edematous papillary tumor covering the right half of the floor of the bladder which extended into the trigone. The right ureteral orifice was obscured by the tumor. Eight months after surgical treatment of the vesical tumor, the patient felt a snap in his right leg and fell. He was admitted to the hospital and placed in traction. Roentgenograms showed a pathological fracture of the right upper femur and extensive destruction of the bone, which was not apparent on a roentgenogram taken six weeks earlier. The patient rapidly grew worse and died nine months after his first admission. The author feels that tumor cells of the primary lesion probably entered the blood stream and were carried to the bone. The literature on bone metastases from vesical tumors is reviewed. The author stresses that metastasis to bone from bladder tumors is more frequent than is generally known. Metastases are apparently blood borne and bear no relationship to the size of the primary tumor. The bony lesions are osteolytic in nature. Radical surgery with removal of pelvic lymphatics is an advance, but is not the final answer to treatment of carcinoma of the bladder.

Fascination: A Cause of Pilot Error.—Fascination is a condition in which a pilot fails to respond adequately to a clearly defined stimulus-situation in spite of the fact that all of the necessary cues are present for a proper response and the correct procedures are well known to him. Fascination has also been defined as a state of narrowed attention associated with excessive concentration on some object or task with resulting loss of voluntary control over response. Thus, a flight student may concentrate on lining up with the runway and keeping a proper attitude to such a degree that the sound of the horn indicating "wheels up" may be so far in the margin of his attention that it is not perceived. Therefore, the pilot does not react appropriately although he may recall later that the horn had blown. The authors were led to inquire into the problem of fascination after discussions with instructors in formation flying, who described experiences in which the student pilot failed to maneuver in order to avoid certain collision. This occurred under circumstances that posed no problem in flying skill. A questionnaire was constructed and was administered to naval flight students, with the explanation that the purpose was to obtain information regarding vertigo and fascination, and the two terms were defined for them. The students were assured that all of their statements would remain confidential and that the results would be for research purposes only. The questionnaire, which asked the students to write a description of an experience with fascination and to mark a check list of such experiences, was administered to a total of 502 flight students, 226 of whom were approaching the end of basic flight training and 276 students in advanced training. In addition, 25 flight instructors were interviewed. Fascination or target

fixation was well known to both instructors and students; it had been experienced by 92% of the advanced students and 88% of the basic students. The phenomenon is more complex than the definition indicates. One type of fascination involves excessive concentration, whereas certain types of fascination experiences involve also compulsive behavior and "blocking." It is suggested that fascination as a hazard in flying can be reduced by the flight student being taught to shift his attention from one significant thing to another in his visual and auditory fields, by techniques that reduce tenseness and by knowledge of what fascination is and of how to deal with it. Fear and the emotional reactions accompanying it, and the resulting emotional "blocking" plays a part in fascination, particularly in the early stages of learning. Such reactions should be guarded against and will tend to be reduced in the normal process of learning.

Treatment of Simple Goiter with Thyroid.—A summary is presented of the medical literature on treatment of simple goiter with thyroid since the inception of such therapy in 1894. In view of the current infrequent use of thyroid in simple goiter, 50 patients between the ages of 11 and 70 years with simple nontoxic goiter are reported who were treated with thyroid between 1945 and 1950. Of the 50 patients, 23 had diffuse goiter, 9 multinodular goiter, and 18 a single nodule. The usual dose of desiccated thyroid was 2 or 3 grains (0.12 to 0.2 gm.) daily, with the extremes varying between $\frac{1}{2}$ and 6 grains (0.03 to 0.4 gm.) per day. The patients were reexamined at intervals that varied from one week to two months, and therapy was continued until no further decrease in the size of the thyroid gland seemed likely or until the goiter had disappeared altogether. As an exactly comparable series of untreated patients could not be accumulated, a survey was made of the hospital

records of all patients admitted since 1933 with simple nontoxic goiter. Letters were sent to these patients, and the 40 who returned for reexamination were used for comparison. Of the 50 patients treated, 12 were therapeutic failures, while the size of the thyroid decreased in 38, with complete remission in 20. Most of the complete remissions occurred within three months, and none required more than six months. Most of the patients who failed to show any response were treated for longer than six months. It is unlikely that a prolongation of therapy would have been effective. Only two relapses were observed during the one to seven years of follow-up. Although it is anticipated that more will occur in the future, such relapses should be amenable to another course of thyroid therapy. Twenty of the 23 patients with diffuse goiter responded to the treatment, and 10 underwent complete remission. Six of the nine patients with multinodular goiter had a favorable response, and in three the goiter disappeared completely. Diminution in the size of the goiter occurred in only 6 of the 40 patients who had not been treated with thyroid. The results of earlier investigators concerning the usefulness of the thyroid in the treatment of simple goiter were, therefore, amply confirmed by the authors' observations. The age of the patient and the duration of the goiter prior to treatment did not seem to have as great an influence on the response to therapy as was previously observed. Many of the patients with a satisfactory response to the treatment were in the older age groups and had noted thyroid enlargement for 5 to 10 years or longer. Diffuse goiter proved more apt to respond than the nodular variety. Desiccated thyroid will decrease the secretion of thyrotropin and, in turn, the size of the goiter, regardless of the nature of the defect in hormone synthesis; therefore, it might be regarded as specific in the treatment of goiter. In addition to its beneficial effect on the size of the goiter in three out of four cases, thyroid administration aids in diagnosis in doubtful cases. Failure of the goiter to respond and failure of the radioiodine accumulation to be suppressed constitutes suggestive evidence for diagnosis of hyperthyroidism.

Bilateral Paralysis of Vocal Cords.—Preoperative examination of the vocal cords of a large number of patients who were to undergo thyroidectomy and corresponding postoperative examination of the same patients 10 to 14 days later, by indirect laryngoscopy revealed that 88 patients had experienced paralysis of a vocal cord. An inquiry was made regarding any untoward symptoms these patients might have had during the early postoperative days. For comparison 1,300 records of patients without vocal cord paralysis were available. It appeared that if a patient who has had a thyroidectomy is hoarse and also suffers from choking during the first five postoperative days, it is highly probable that at least one vocal cord has been paralyzed. Six months or more after one vocal cord has been paralyzed at thyroidectomy the patient probably will have no symptoms referable to such paralysis. Six months or more after both vocal cords have been paralyzed at thyroidectomy the patient's voice usually will be essentially normal, but he will have more or less dyspnea. This results because the bowing of the vocal cords that at first results from the surgical paralysis gradually changes so that the margins become nearly straight with gradual reduction in the airway between the cords. Treatment for bilateral paralysis of the vocal cords is indicated whenever the patient cannot live comfortably within the limitations imposed by the dyspnea. Two methods of surgical treatment are available: (1) the King operation, whereby the arytenoid is removed or is anchored laterally, with the field of operation exposed through an external excision and (2) the Thornell operation, a transoral arytenoidectomy, with the field of operation exposed by means of the suspension laryngoscope. The latter technique was employed by the author in 50 patients with bilateral paralysis of the vocal cords with excellent results in 47, fair results in 2, and unsatisfactory results in 1. Good results can be achieved by either method.

Painful Injections Allayed with Cortisone.—Cornbleet found that a drop (1/20 cc., 1.25 mg.) of ordinary commercial suspension of cortisone or hydrocortisone incorporated with an injectable medicament allays immediate pain. Control injections with the suspending fluids for cortisone and hydrocortisone were of little help, and procaine solutions used with painful materials did not allay pain. However, if anesthetization

preceded the use of the medicament, this prevented pain, but required two injections. The analgesic action of cortisone must be by some other mechanism than that of ordinary local anesthetics. It may perhaps prevent formation of or neutralize intermediate noxious materials, such as histamine-like agents. This would seem to be the case, because cortisone abolishes flare in the skin at the site of its injection. Another possibility is that cortisone shields sensory endings against the effects of injury. The author feels that if others will corroborate the results he obtained, pharmacutists might want to include the corticoids with such painful medicaments as thiamine hydrochloride and crude liver extract.

Cerebral Injury Due to *Trichinella Spiralis*.—Usually infestation with *Trichinella spiralis* manifests itself in puffing of the eyelids, a febrile reaction, muscular pains, and intestinal symptoms. The central nervous system is not often involved, but, when this occurs, the symptom complex can be varied and misleading. Hurd presents the case of a man, aged 40, who on Sept. 5, 1949, ate two patties of ground pork that were insufficiently cooked. Six days later, the patient had a brief bout of slightly bloody diarrhea. The next day his eyes were puffy and red. On the 10th and 11th day after ingestion, he noticed weakness of the right arm and leg and stayed home from work. On the 13th day he could barely walk, was confused, and could not recognize his son. On the following day, he was hospitalized with a provisional diagnosis of poliomyelitis. For the first nine hospital days the temperature ranged from 102 to 103.5 F. On the second hospital day the leukocyte count was 23,700 and the differential count showed 4% eosinophils. The patient was unable to move any muscle in the right arm or leg. On the fifth hospital day, the white blood cell count had fallen to 14,000 with an eosinophilia of 25%. At this time, the story of the inadequately cooked pork was obtained. The high eosinophil count, a positive intradermal test for trichiniasis, and a complement fixation test for trichiniasis with a titer of 800 established the diagnosis. The patient was discharged from the hospital on the 31st hospital day still having some difficulty in walking because of dragging of the right leg. Seven months after discharge there had been no improvement in the right leg, but otherwise the patient appeared normal. The author reviews the literature on involvement of the central nervous system in trichiniasis and shows that in a total of 31 reported cases there were 9 deaths. Patients who have only muscular weakness and in whom reflexes are absent usually recover completely, but the prognosis is poor in patients with mental disturbances or signs of focal lesions in the central nervous system. Trichiniasis with neurological complications may resemble encephalomyelitis, meningitis, acute poliomyelitis, polynueritis, dermatomyositis, and periarthritis nodosa. The methods available for the diagnosis of trichiniasis increase in reliability as the disease progresses. During the first week the chief diagnostic aids are a history of ingestion of raw pork and eosinophilia. During the second week a centrifuged specimen of the cerebrospinal fluid may reveal larvae, if a thorough search is made for them. An intradermal skin test may show a wheal type of reaction. During the third week muscle biopsy and complement fixation tests can be performed.

Metabolic Studies After Bilateral Adrenalectomy.—Butler and associates review the history of the use of endocrine treatment in the management of prostatic cancers and point out that hundreds of patients with prostatic cancer have been treated either by surgical castration or estrogen administration, or a combination of both. It was recognized that many failed to respond or responded only for a short while to castration and/or estrogen therapy. A study of the urinary 17-ketosteroids suggested that after castration a reduction occurred followed by a rise to a level twice that observed prior to castration. This rise suggested an extragonadal source of 17-ketosteroids and androgens. This source was logically the adrenal, and so, bilateral adrenalectomies were performed in patients who relapsed after previous response to castration or estrogen therapy. With the aid of cortisone and a certain regimen patients could be kept alive without adrenals. Butler and associates studied the metabolic effects of bilateral adrenalectomy and describe the subjective and objective responses in two patients. They conclude that bilateral adrenalectomy can be a safe and valuable procedure. It may prove to be of great value in the therapy of carcinoma of the prostate, hyperten-

sion, and diabetes mellitus, but until the physiology of the adrenalectomized patient is better understood it must be restricted to the cases in the hopeless category. Patients who have had bilateral adrenalectomy may be maintained on 25 to 50 mg. of cortisone given orally each day in two doses. Acid-base balance remains in equilibrium at this dosage when renal function is normal and the diet is adequate and contains 6 gm. of sodium chloride. Desoxycorticosterone is not usually required and even appears to be contraindicated by studies of total sodium and potassium excretion. Glucose tolerance is increased after bilateral adrenalectomy when cortisone dosage is 25 mg. a day. Alkaline and acid phosphatases indicated improvement of two patients with carcinoma of the prostate with metastases after bilateral adrenalectomy. Another indication that there was a decrease in the cancer growth rate or metabolic rate was the ability of these patients to maintain total serum protein and hemoglobin values. Testosterone increased the adrenocortical requirement and precipitated an Addisonian crisis twice in one of the patients without adrenals. The 17-ketosteroid excretion decreased but never reached very low levels after adrenalectomy. In the second patient, when the malignancy of the prostate became autonomous during the exacerbation, there was an increase in the 17-ketosteroid excretion.

Six Functioning Kidneys in a Woman.—The patient whose case is presented is a woman, aged 42, who enjoyed such excellent health both before and after the incident of central abdominal colic, which led to the x-rays being taken, that she saw no reason for further investigation to satisfy the curiosity of science. However, the pictures clearly indicate that the six kidney-ureter units consist of two sets of three each. There is a medial group consisting of a single right and a double left unit and a lateral group that also shows a single kidney on the right and two on the left. The medial one taken alone would not excite interest because it reproduces a very common clinical finding, namely a double kidney and two ureters on one side. The two ureters run close together and reach the bladder at approximately the same place. In the lateral group, on the other hand, all three ureters pass out widely and maintain a course far lateral to the normal one. They originate from no well-defined kidneys but a series of tube-like calyces that pass mediolaterally, in contrast to the usual arrangement as seen in the medial group. At their lower ends, these lateral ureters turn sharply toward the middle line, cross the medial ureters, and seem to course toward the region of the bladder neck. The two left lateral ureters run side by side and appear to cross one another at least once. The author speculates on the embryonal disturbance that could have produced such an unusual urinary tract and still left the general health unimpaired. He discusses the following hypotheses: 1. There were only two mesonephric ducts, but two ureteric buds arose from the right one and four from the left. 2. The lateral ureters represent a mesonephric system that has continued to function in the adult. The mesonephric duct of the left side is duplicated. 3. There were four mesonephric ducts in the embryo, two on each side. The ones on the right side gave rise to one ureteric bud each, those on the left to two each. 4. The extra kidneys and ureters represent a teratomatous formation, and there is a "duplicata infraumbilicalis" present with no manifestations outside the urinary tract. The author feels that none of these hypotheses are satisfactory.

Hexamethonium and Hydralazine (Apresoline) Hydrochloride.—Thirty hypertensive outpatients were chosen to demonstrate the effects of hexamethonium chloride (Esomid) and hydralazine (Apresoline) on essential hypertension and their adapta-

bility to a regular regimen for the ambulatory hypertensive patient. Of this group, 21 patients had significant responses to the initial dose of 250 mg. of hexamethonium every 12 hours. Twenty-four patients complained of side-effects of the drug, and five patients refused to continue the program because of them. The effects included postural dizziness, blurring of vision, weakness, headache, and constipation; they usually disappeared after the first few weeks of treatment. Two patients had one or more syncopal attacks six weeks after the beginning of treatment. Of the 25 patients who allowed their doses of hexamethonium to be increased and combined with hydralazine, 2 had significant maintained responses and 1 was not followed up for a sufficient period to be included in the report on maintained response. It is certain that both hexamethonium and hydralazine are powerful hypotensive agents, hexamethonium being the stronger. Their ability to produce a significant initial fall in blood pressure is more reliable than their long-term effect, and the likelihood of the occurrence of the latter is unpredictable for any given patient. The authors believe that a regimen for the properly informed ambulatory hypertensive patient can eventually be worked out, but the problems arising from the administration of hypotensive agents to hypertensive patients must be further studied. These include fluctuation in blood pressure and severe consequences of hypotension or rapid fall in blood pressure, as well as the failure of the drugs themselves in the maintenance of effective relative hypotension.

Occult Dislocation of Ankle.—Although most ankle sprains are relatively minor injuries, occult dislocations of the ankle occur more frequently than supposed and are serious injuries. After a forcible inversion of the ankle, the lateral ligaments are often partially or completely torn, allowing the talus to dislocate from the ankle mortise without fracture of any of the bones making up the ankle joint. In all except rare cases following severe trauma, such a dislocation is reduced spontaneously by the pull of the peroneal muscles. The usual roentgenographic examination shows no fracture or deformity of the ankle joint, and the diagnosis, by exclusion, is "sprained ankle." The symptoms are similar to those of a sprain, but usually severer. Swelling and ecchymosis usually occur at the site of, and distal to, the point of injury. Pain is a usual occurrence and is aggravated by motion of the affected part, especially motion in the direction of injury. The examiner may frequently be able to palpate a sulcus below the lateral malleolus and feel the talus tip out of the mortise as he inverts the ankle in the direction of injury. Oftenest there is point tenderness over the involved ligament. Frequently a large subcutaneous hematoma develops rapidly. If occult dislocation of the ankle is suspected, diagnosis can be confirmed by an anteroposterior roentgenogram taken while the ankle is forcibly inverted in the direction of the injury; this technique is difficult. Immobilization in plaster should be used in recent dislocations; chronically unstable ankles subject to recurrent "sprains" may require surgical repair.

*Acute Adrenal Insufficiency During Pregnancy. J. Plotz.—p. 61.

Acute Adrenal Insufficiency During Pregnancy.—Plotz says that acute adrenal insufficiency develops not only in meningococcal sepsis but also in other infectious diseases. A survey of the recent literature convinced him that acute adrenal insufficiency is more frequent in pregnant and puerperal women than is generally realized. He reviews 56 fatalities in pregnant and puerperal women resulting from hemorrhage, infarction, necrosis, or thrombosis of the adrenals. Nine of these cases were observed at the Women's Clinic of the University of Hamburg and accounted for 3.6% of the obstetric fatalities. Anatomic studies disclosed extensive destruction of the adrenals, the parenchymal structure being practically obliterated. The majority of the patients died during the puerperium. The onset of the syndrome is sudden and characterized by severe collapse, cyanosis, vomiting, and abdominal or lumbar pain. Other disorders or complications in the form of toxemia, postpartum hemorrhage, puerperal septicemia, pyelonephritis, hyperemesis, pneumonia, or crush syndrome, were present in 51 of the patients. The prognosis of acute adrenal insufficiency is generally regarded unfavorable. The author suggests the following therapeutic measures: intravenous injection of 20 cc. of adrenal cortex extract, intramuscular injection of desoxycorticosterone acetate and 50 mg. of cortisone acetate, also drip infusion of dextrose and isotonic sodium chloride solutions, antibiotics to combat infection, and measures to counteract shock.

Damage Done to Pancreas by Carbon Tetrachloride.—Involvement of pancreas in carbon tetrachloride poisoning is reported in a 34-year-old male nurse and in a 32-year-old female nurse who did not use protective masks when they sprayed a contact insecticide with a hand nebulizer over several rooms of a home for the aged. The insecticide contained carbon tetrachloride as carrier substance besides small amounts of γ -hexachlorocyclohexane and pyrethrum. Initial listlessness similar to alcoholic intoxication occurred in both patients. It was followed by disturbances of the liver and the circulation characteristic of carbon tetrachloride poisoning, while there was no decrease in function that might have suggested organic damage to the central nervous system. Tenderness of the enlarged liver, combined with bilirubinuria and a positive aldehyde test were observed in the man nine days after the poisoning. Toxic damage to the liver was confirmed seven weeks later by the behavior of the serum bilirubin and cholesterol and the still increased size of the organ. At the same time involvement of the pancreas was revealed by tenderness on pressure in the left epigastric region, left side Head's zone, burning pain after injection of 3 cc. of ether into the duodenum, definite ferment derangement and rise in blood sugar after the first and second dose of dextrose. On follow-up examination 10 months after the poisoning the disturbance of the pancreas had not yet completely subsided. Signs of damage, sustained by parenchyma of the liver in the woman were similar to those in the man, while indications of involve-

ment of the pancreas, although less pronounced than in the man, justified consideration of toxic damage to the pancreas. An atypical pancreatitis was observed by Moon on necropsy done in five cases of fatal carbon tetrachloride poisoning. Vegheli and co-workers produced degenerative lesions of the pancreas in rats by carbon tetrachloride.

Mortality from Lung Cancer Among Nonsmokers.—A nonsmoker is defined as a person who has never consistently smoked for as long as one year at the rate of as much as one cigarette or 1 gm. of tobacco a day. Estimates of the mortality rates from lung cancer among nonsmokers were obtained from the Registrar-General's figures for the number of deaths attributed to lung cancer and from the data obtained in a clinical inquiry into the proportion of nonsmokers among patients with bronchial carcinoma and among patients with other diseases (excluding cancer of the oral cavity, respiratory tract, or intrathoracic organs). The assumptions required to enable the estimates to be made are bold, and the number of cases of bronchial carcinoma among nonsmokers is small. The rates obtained are, therefore, highly speculative, but it is thought that they are likely to be reasonably reliable since they are consistent with other experience. It is concluded (1) that one in five of the lung cancer deaths that occurred in persons aged 25 to 74 years, in 1950, may be attributable to causes other than smoking; (2) that the incidence of lung cancer in nonsmokers may be the same in men and in women and in residents in areas of different density of population; and (3) that occupational hazards and the previous occurrence of certain respiratory diseases are unlikely to be of frequent etiological importance.

Effects of Cortisone and Corticotropin on Skin Bruises.—Lovell and his associates point out that Cushing in 1932 described hemorrhages in the skin as a feature of the syndrome that bears his name. Apparently spontaneous bruises also occur in some patients receiving cortisone and corticotropin. When Lovell and associates first saw these lesions in two patients,

one receiving cortisone and the other corticotropin, they thought the discoloration persisted for an unusually long time. Bruises produced by venipuncture also disappeared very slowly. The observations led them to study the effects of cortisone and corticotropin on the dispersion of bruises induced experimentally in the skin. Studies in man confirmed their original observation; the hormones delayed dispersion of experimental bruises, and delay also occurred in Cushing's syndrome. In guinea pigs bruise dispersion was likewise delayed by cortisone. The results of histological studies make it unlikely that the effect can be attributed to impairment of macrophage activity. The effect may be due to impaired lymphatic removal of erythrocytes or to altered resistance to their dispersion through the ground substance of connective tissue.

Surgical Treatment of Suppurative Hidradenitis. D. W. Williams.—p. 231.

Reactions of Tissues to Thiersch and Other Grafts.—This extensive report is concerned with the spontaneous healing in man of Thiersch donor sites, of long-standing exuberant granulations following burns and of the response in wounds and the alterations in the healing process in such injuries induced by the application to them of auto-Thiersch grafts and/or autodermal and/or homodermal grafts. This analysis is based on the clinical study of 3 patients with burns, of 30 patients who had had various types of grafting operations performed, and of experiments conducted on 6 volunteers. The histological material examined comprised a total of 36 biopsies of healing Thiersch graft donor sites and of granulation tissue treated with Thiersch and other types of grafts, 48 biopsies taken from the volunteers at different time intervals after the operation of Thiersch graft removal, and the application of various types of grafts to the donor sites and 15 biopsies of scars and keloids of various ages. Most of the material studied histologically was serially sectioned. Comparing the histological appearances of Thiersch donor sites at various times up to eight years after removal of such grafts with the original histological appearance of the skin of the graft donor site revealed that even after eight years the skin in the graft donor site is not reconstructed to acquire its original morphology. The histogenesis of the healing process in the Thiersch donor site is described. Long-standing exuberant granulations, which develop in burn sites, undergo radical morphological changes after the application of auto-Thiersch grafts, autodermis, or epithelium. The epithelium of Thiersch graft "stamps" applied to such granulations becomes markedly acanthotic, invades the underlying fresh granulations, forms epithelial pearls, and also grows across the neighboring granulations. The epithelial connective tissue relations in healing wounds indicate that the healing of a wound is dependent on the maintenance of a very delicate balance of relations between the connective tissues and the epithelium. The significance of the described changes for an understanding of the etiology and pathogenesis of normal scars, hypertrophic scars, keloids, epithelial neoplasms, and other dermatological conditions is discussed. It is suggested that the supervision of scars in sites of injuries is determined in large measure by the depth of the lesion that affects the nature of both the connective tissue and the epithelial responses to injury. This effect of deep lesions is not dependent so much on the extent of epithelial or dermal destruction as on the alteration in connective tissue-epithelial relations in wound healing induced by a deep wound. Some of the local and systemic hormonal factors affecting the nature of the healing process are discussed. The possible role of damage to dermal tissue, as opposed to epithelial irritation, in relation to the etiology and pathogenesis of irradiation injuries, lupus, and carcinomas of the skin are also discussed.

Valvotomy for Mitral Stenosis.—Mitral valvotomy was performed on 31 men and 119 women between the ages of 19 and 57 years with mitral stenosis. Four of the 150 patients operated on died within four days as a direct result of the operation, an immediate operative mortality of 2.7%. Four patients died of various causes one month or longer after the operation. Of the 150 patients, 111 were followed up for five months to two and a half years. Good results with relief from symptoms, such as paroxysmal dyspnea, orthopnea, and hemoptysis, and a considerably increased capacity for effort were obtained in 81 (74%) and only fair or poor results in 22 (20%). The remaining 39 patients have been operated on within the last three months; all have made satisfactory progress, but it is too early to evaluate the results. Sixty-two (41%) of the 150 patients had auricular fibrillation; the functional results obtained in these patients were as good as in those with sinus rhythm, but 3 of the 4 operative deaths occurred in fibrillating patients. The basic indication for mitral valvotomy is disability from mitral stenosis of an anatomic form that is amenable to surgical correction. This type of stenosis in which the two segments of the mitral valve are united and stretched like a diaphragm across the auriculo-ventricular opening and, apart from the thickened orifice, the mitral diaphragm is relatively pliant (pliant diaphragmatic valve), gives rise to characteristic clinical signs by which it may be recognized as follows: a snapping apex beat, a snapping first sound (closing snap), and a loud opening snap of clicking quality following closely the second sound. Additional evidence of severe mitral stenosis is provided by intense diastolic and presystolic murmurs, a sustained pulse, and a small hypoplastic aorta in the radiogram. The most important consequence of pulmonary hypertension is right ventricular enlargement and the size of the right ventricle, as determined by clinical, radiological, and electrocardiographic findings, provides a more valuable index to the degree of pathological change resulting from mitral stenosis than does the level of the pulmonary arterial pressure at a given moment. Cardiac catheterization is no longer required as a routine measure in the selection of patients suitable for mitral valvotomy. Selection may now be made on a basis of the symptoms and of the data provided by routine cardiological examination. The authors' patients selected for operation on grounds of an operative valve were classified according to the size of the right ventricle and the presence of congestive failure. Patients with large hearts and congestive failure that did not respond to treatment benefited least from valvotomy. When free splitting of the commissures was achieved, 84% of the patients obtained good symptomatic relief; when valvotomy was judged at operation to be less satisfactory, only 46% of good results were obtained. Nevertheless, partial splitting of the valve does not preclude satisfactory clinical improvement. Good results were obtained alike in those with greatly elevated pulmonary arterial pressures and in those with a slight or moderate elevation.

Specific Bacteriolysin in Subacute Bacterial Endocarditis.—A case of subacute bacterial endocarditis in a 33-year-old woman with persistent anemia (7 gm. hemoglobin per 100 cc.) is described in which there was serologic evidence that the

causal organism was a hemolytic coagulase-negative strain of *Micrococcus* (*Staphylococcus*) *albus*. In vitro tests showed that the organism was sensitive to penicillin; 1,000,000 units of penicillin was given daily for five weeks. The patient's condition improved dramatically with this therapy. For some months she continued to be well, but then was readmitted to hospital with severe decompensation. Gross cardiac failure developed and death occurred. Permission for necropsy was refused. The striking feature of the strains of *M. albus* isolated from the patient's blood cultures was the degree of hemolysis produced on blood agar. The patient's serum was studied for antibody content. Results showed that the serum did not contain any agglutinins but that a bacteriolysin was present, which was evidently specific for the *Micrococcus* isolated from the blood cultures. The anemia of the patient was undoubtedly due to the hemolytic activity of the *Micrococcus*. The development of specific bacteriolysin does not appear to have been reported in other similar cases and may be a purely isolated finding. Absence of postmortem data makes it difficult to assess the effect of the septicemia on the course of the patient's illness, but the degree of cardiac damage was so great that it is feasible to assume that early death was inevitable, irrespective of the blood infection.

*Cholechochoplasty with Polyethylene Tube. R. Palomba.—p. 495.

Polyethylene Tubes in Cholechochoplasty.—Polyethylene tubes proved satisfactory in plastic surgery of the biliary tracts. Their use was especially valuable when surgery was performed for stenosis of the common bile duct and Oddi's sphincter. In such cases plastic surgery over the polyethylene tube inserted through the papilla is preferable to the use of temporary external drainage tubes. Removal of rubber tubes may be difficult and may cause complications such as fistula and secondary cicatricial stenosis. The author cites two cases in which he used this technique and obtained good results. An inflammatory sclerosis of the sphincter of Oddi was present in the first patient, a 69-year-old woman, in whom surgery had previously been performed for biliary lithiasis. A sphincterotomy and plastic surgery of the opening of the common bile duct were performed. To insure good internal drainage of the bile and to facilitate normal healing of the opening of the common bile duct, a polyethylene tube was inserted into it. There were no side-effects attributable to the presence of the polyethylene tube, and a follow-up five months later indicated perfect restoration of the bile flow. In the second patient, a 59-year-old man, the duodenal opening of the common bile duct was obstructed by an adenocarcinoma of the papilla of Vater. The tumor was removed, the common bile duct was sutured circularly to the duodenal mucosa, and a polyethylene tube, opening into the duodenum, was inserted. Since a local recurrence of the tumor was feared, a cholecystogastrostomy was performed. The presence of the tube was well tolerated, and an optimum flow of bile into the digestive tract was obtained. It was difficult, however, to evaluate how much the good results in this patient were to be ascribed to the transpapillar drainage through the polyethylene tube and how much to the cholecystogastrostomy.

*Experimental Contribution to Study of Action of Ganglioplegics Used for Controlled Hypotension. E. Genazzani and A. Russo.—p. 547.

Action of Ganglioplegics in Controlled Hypotension.—The authors performed a series of experiments on rabbits to establish (1) the acute toxicity of bitartrate of hexamethonium, (2) its true efficacy in determining hypotension and abolishing

vasomotor reflexes, and (3) the influence of various anesthetics on the pharmacological activity and the toxicity of this salt. The drug administered intravenously in divided and successive doses killed the animals that had not been anesthetized with doses of 53.52 mg. per kilogram of body weight. The animals that received the salt by intravenous perfusion at a constant velocity died with an average dose of 44 mg. per kilogram of body weight. All the anesthetics used (urethane, chloroform, ether, and Farmotal) increased the toxicity of the salt. Animals anesthetized with Farmotal died with a dose of 6.24 mg. per kilogram of body weight. The drug had a depressing action on the respiration, and this action was more pronounced in those animals in which anesthesia was obtained with drugs that inhibited the respiratory center. Caution should be used in administering these drugs to patients whose respiratory function is impaired. As for the efficacy of the salt to determine a lasting and controllable hypotension, in no case was it possible to obtain a constant, marked, and lasting hypotension even when the doses were gradually increased. Moreover, especially in the animals that had not been anesthetized and in those that received urethane, the arterial pressure always had a tendency to return to elevated values. The specific ganglioplegic action was studied with reference to the carotid sinus reflexes and the reflexes of posture. The drug never had a paralyzing action on them, and, although the smaller doses inhibited them, elevated doses brought them back to normal and sometimes increased them. The authors doubt the value of these actions and they suggest caution in using them in the anesthesia field.

*Tuberculous Meningitis. J. Murphy.—p. 122.

Duodenal Fistula. T. O'Neill.—p. 135.

Differential Diagnosis of Haemoptysis and Its Management. C. S. Breathnach.—p. 139.

Shortcomings of Obstetric Service of National Health Scheme in Great Britain. J. G. O'Sullivan.—p. 147.

Tuberculous Meningitis.—Tuberculous meningitis is essentially a disease of children, usually associated with or derived from the primary tuberculous infection that generally occurs in childhood or young adult life. Of the author's 12 patients with tuberculous meningitis, 4 were less than 3 years of age, 1 was between 3 and 5 years, 2 were between 5 and 9 years, and 5 over 9 years. All 12 patients had positive reactions to tuberculin tests. Four of the 12 patients had miliary tuberculosis, which is also an early complication of the primary infection and usually occurs before meningitis. The prognosis is much worse in the presence of miliary spread. Early clinical manifestations of tuberculous meningitis frequently consist of vague abdominal pain and vomiting that are suggestive of an abdominal rather than a neurological lesion. When tuberculous meningitis progresses, signs and symptoms of meningeal irritation and increased intracranial pressure develop; severe headache and generalized convulsions are common. Repeated lumbar puncture is essential to detect latent tuberculous meningitis. The author used lumbar puncture routinely without ill-effect at two week intervals during the first three months and monthly during the subsequent three months. Tubercle bacilli were found on direct examination of the cerebrospinal fluid in 8 of the 12 patients, and by culture in 1. Eight of the 12 patients died, and in 3 tubercle bacilli were not recovered. Treatment with streptomycin should not be withheld on the failure to find the organisms, if other aspects of the case support the diagnosis. Streptomycin and *p*-aminosalicylic acid are accepted as the standard form of treatment. There can be no hard and fast scheme of dosage or rhythm of injections. The present trend tends toward a longer total period of treatment with more frequent rest periods, i. e., intramuscular administration for six months with rest period commencing at the end of the second month, and intrathecal treatment for four and a half months with rest period commencing at the end of the second month. Systemic treatment should not be stopped until the sugar level of the cerebrospinal fluid has reached 50 mg. per 100 cc. Hyaluronidase

mixed with streptomycin was given intrathecally to three patients with spinal block, but it is difficult to assess its value in this small number of patients. A 20% solution of *p*-aminosalicylic acid sodium in doses of 7.5 cc. was administered intrathecally on alternate days to a 14-year-old boy with prolonged pyrexia in addition to *p*-aminosalicylic acid orally and dihydrostreptomycin intramuscularly and intrathecally. The patient's temperature was restored to normal within a few days and remained normal. Isoniazid was used in one patient with definite benefit and no apparent side-effects. Four (33.3%) of the author's patients recovered. The average recovery rate in this series and in four additional series of patients collected from the literature was 50%. Improved results will not necessarily depend on the discovery of new drugs. Earlier diagnosis, to limit the formation of basal exudate and to prevent irreparable brain damage, must again be stressed. The wider use of BCG vaccination should help to lower the incidence of the disease in the younger age groups. Tuberculous meningitis is a combined problem and involves the cooperation of the general practitioner, hospital medical staff, and public health authorities.

Influence of Folic Acid in Absorption of Iron.—Begemann and associates describe studies on healthy subjects and on persons with various disturbances that were designed to ascertain whether and under what conditions folic acid promotes the enteral absorption of iron. Iron was administered in the form of 200 mg. of ferrous sulfate. It was found that the increased absorption of iron that prevails in conditions of iron deficiency is further improved by the administration of folic acid. The absorption of iron was improved also in patients with gastric anacidity or subacidity, that is, in conditions in which the absorption of iron is greatly impaired. The tolerance for orally administered iron is greatly improved by the simultaneous administration of folic acid. The mode of action by which folic acid improves the resorption of iron, however, is not yet fully explained, but since it is known to promote the absorption of other substances, it is assumed that folic acid acts by modifying cellular permeability. The authors were interested chiefly in ascertaining the influence of folic acid on iron resorption and thus to clarify the indications for its therapeutic administration.

Dextran Sulfate: Synthetic Heparin Analogue.—The naturally occurring anticoagulant, heparin, is the sulfuric ester of a complex polysaccharide. Some investigators showed that the sulfuric esters of other polysaccharides have a similar but

weaker anticoagulant activity. Sulfuric esters were prepared from dextrans of various molecular weights by Grönwall and associates who reported that the toxicity of their compounds declined as the molecular weight decreased; but they did not produce a satisfactory therapeutic compound. Further studies on dextran sulfate revealed that molecules of optimum size and sulfur content, though less potent, weight for weight, than commercial heparin, behaved in a qualitatively similar biological fashion and showed comparably low toxicity. The results obtained with dextran sulfate in the first three cases were considered sufficiently encouraging to warrant further trial. Material was supplied to three centers with considerable experience of anticoagulant therapy with heparin, for independent assessment. The response in the 24 persons to whom dextran sulfate was administered during the various clinical trials indicates that dextran sulfate serves as an effective anticoagulant in clinical practice. The clotting time response to intravenous injection resembled that to equipotent doses of heparin in that intermittent dosage produced a "picket-fence" curve, and continuous infusion gave a smooth curve adjustable to any given level by appropriate adjustment of the rate of administration. The most noticeable difference was that of duration of effect. Heparin administered intravenously in a dose of 5,000 I. U. prolonged the clotting time for two or three hours; the equivalent dosage of dextran sulfate produced an effect for five to seven hours. The material used in the clinical trials was assayed in terms of heparin units. This was an interim measure for the convenience of clinicians accustomed to heparin dosage and to facilitate the comparison of equipotent doses of the two anticoagulants. In view of the observed difference in duration of effect a sample of dextran sulfate has been submitted to the World Health Organization Committee on International Biological Standards with a proposal that a provisional standard be established for dextran sulfate itself. No serious side-effects have been observed.

Hypothermia: Experimental Surface Cooling.—The difficulty of maintaining an adequate flow of oxygenated blood to the vital organs during complex surgical operations is one barrier to further advances in cardiac and cerebral surgery. Hypothermia, by reducing the body temperature and consequently the metabolism, is one means of attaining this end that has been used on a limited scale for many years. Surface cooling appeared to be the simplest and safest method. An investigation was undertaken to reassess the possible dangers before its application to surgery in man. Thirty unselected mongrel dogs weighing 8 to 15 kg. were used. After the dogs had been anesthetized and the trachea intubated, control readings of body temperature, pulse rate, blood pressure, electrocardiogram, and oxygen consumption were taken. The dog was next immersed in a bath of water at about 18 to 20 C (64 to 68 F). Crushed ice was added after a few minutes so that the temperature of the water rapidly fell to 2 to 6 C (36 to 42 F). Twenty dogs (series 1) were cooled in this manner until their rectal temperature had fallen to 24 C (75.2 F), when they were stabilized at 22 to 24 C (72 to 75.2 F) for at least 30 minutes before being rewarmed. Ten dogs (series 2) were cooled in an identical manner to 28 to 26 C (82 to 78 F) for a similar period and then rewarmed by raising the temperature of the water in the bath to 42 C (107 F). On the basis of these investigations the authors arrive at the following tentative conclusions: 1. Surface cooling is the simplest method of inducing hypothermia. 2. Until some method is found to prevent ventricular fibrillation, the body temperature should not be reduced below 26 C, and in all cases in which hypothermia is used continuous electrocardiograms should be displayed. 3. Hypothermia may offer an advance in surgery for operations requiring temporary occlusion of the great vessels, but the increased "irritability" of the cardiac muscle at temperatures of 25 C (77 F) and below is the chief risk of operations on the heart under these conditions. The age of the animal is of particular importance, for the younger the animal the greater the margin of safety.

- *Our Experience with Surgery of Aneurysms of the Internal Carotid and Its Branches Since Using Ganglion Blocking Agents. Laine, Delandtsheer and Delandtsheer.—p. 147.
 Can Tuberculosis of the Kidney Be Cured by Medical Means? Macquet, Wemeau, G. Lemaître and DeFrance.—p. 161.

Surgical Treatment of Aneurysms of Internal Carotid and Its Branches.—The treatment of intracranial aneurysms is still hazardous in spite of the efforts at improvement made by neurosurgeons. Pedicled aneurysms can often be removed fairly easily after ligation or clipping of the pedicle, but aneurysms of the internal carotid or the basilar trunk and their branches are almost always sessile, and attempts to exclude them by the use of clips are certain to fail. Various neurosurgeons, including the authors, have tried to halt the progressive distention of the aneurysmal sac and to prevent its rupture by sheathing it with a layer of muscle. This procedure apparently improves the outlook for most patients, but it does not provide absolute assurance against rupture and it is always difficult and dangerous to carry out. Palliative treatment in the form of carotid ligation is, therefore, relied on by most neurosurgeons, although it too may be accompanied or followed by serious or even fatal accidents. Circulatory decompensation resulting in hemiplegia might also develop as a late result of carotid ligation. The continued efforts of the authors to treat intracranial aneurysms by direct approach have been greatly helped by the use of ganglion blocking agents. The dangers of cerebral ischemia can be avoided by not attempting to secure a completely bloodless operation. The results obtained in a new series of 14 patients operated on under conditions of controlled hypotension have been highly encouraging. There were only two deaths, and these occurred in comparatively old, arteriosclerotic patients. Neurological complications followed the operation in two cases, but regressed to the point where they no longer interfered with normal living. Preoperative neurological complications, however, such as hemiplegia, aphasia, and hemianopsia, did not always respond satisfactorily, and in one case they were so severe that the patient remained bedridden. Every effort should be made to discover intracranial aneurysms in time to prevent the recurrence of hemorrhage. Arteriograms should be made within four or five days after the first accident. All the arterial territories can easily be explored by percutaneous arteriography, and, if, as rarely happens, there is no neurological sign to point to the seat of the aneurysm, they should be investigated one by one until it is found. Only in this way can the patient be operated on while still in good condition and with an improved operative prognosis.

- Familial Form of Xanthomatosis Tuberosa. J. W. Bruins.—p. 2651.
 *Aids in the Diagnosis of Pheochromocytoma. J. de Graeff, A. A. H. Kassenaar and A. Querido.—p. 2658.

Diagnosis of Pheochromocytoma.—The case history presented by de Graeff and associates emphasizes how important it is to think of the possibility of pheochromocytoma whenever hypertension is discovered. The patient was a woman, aged 23. The first attack of severe headache appeared three years previously, and such attacks recurred at constantly shorter intervals. There was hypertension and tachycardia, severe pathological changes in the retina, and normal renal function. At first malignant hypertension was suspected, and treatment with a methonium preparation was instituted, but the blood pressure increased rather than decreased. The intravenous injection of 12.5 mg. of piperoxan was followed by a decisive fall in blood pressure, which in turn was followed by the hypertensive "overshoot." Bimanual palpation revealed a mass on the right kidney. Palpation of it caused extremely unpleasant sensations, the patient's skin became clammy and ash-colored, she complained of a bursting headache, and her blood pressure rose to 280/180 mm. Hg, whereas before the bimanual examination it was 170/120. The result of the intravenous injection of 1 mg. of regitine was comparable to that of 12.5 mg. of piperoxan. The "overshoot" after the initial decrease

in blood pressure caused some anxious moments. A brownish-red, highly vascular tumor the size of a tennis ball was removed from the right adrenal, and immediately afterward the blood pressure fell to 110/70. The tumor weighed 120 gm. and contained 650 mg. of arterenol (nor-epinephrine). The authors stress the value of the aforementioned drugs and of an increase of pressor amines in the urine as important aids in the diagnosis of pheochromocytoma. In the case described the pressor amines showed a twentyfold increase.

- *Research Studies on Resistance of Pathogenous Staphylococci to Some Antibiotics with Particular Reference to Penicillin. L. Ortona.—p. 1265.
 Fractures of Base of First Metacarpus. A. Motta.—p. 1274.

Staphylococci and Their Resistance to Antibiotics.—Resistance of micrococci (staphylococci) to antibiotics, especially penicillin, was studied in 100 patients with pyogenous infections. The role played by antibiotic therapy in the causation of this resistance and the results obtained in the treatment of patients with these infections were also studied. Pus, urine, buccopharyngeal mucus, and sputum taken from patients with abscesses, boils, osteomyelitis, urinary infection, and bronchopneumonia were planted on an agar-blood culture plate and were placed in a thermostat at 37° C for 24 hours. A bacteriological examination of these cultures revealed the presence of *Micrococcus* (*Staphylococcus*) *aureus* in 56 of them and *Micrococcus albus* in 21; there were *Bacterium coli* in five, *Bacillus pyocyaneus* in two, and *Streptococcus pyogenes* in four; and there were no bacteria in 12. Of the 77 *Micrococcus* strains, 72 were coagulase positive. Maximal resistance to penicillin was found in 15 strains and relative resistance in 7; 18 of these strains were of the *aureus* type and 4 of the *albus* type. There was resistance in 11 of 18 strains obtained from patients in whom penicillin therapy had been carried out before the micrococci were isolated, and in 11 of 54 strains obtained from patients in whom no therapy was carried out previous to isolation of the bacteria. The clinical course of the infection was followed in 16 of 22 patients in whom penicillin resistance had developed. The drug was not effective in 11 patients in whom the micrococci were resistant to concentrations greater than 10 Oxford units per cubic centimeter. It was effective in five patients with relative resistance when administered in large doses and for long time. As for other antibiotics, maximal resistance to streptomycin was found in two strains and relative resistance in five. Relative resistance to chlortetracycline (Aureomycin) and oxytetracycline (Terramycin) was found in three strains respectively. All the strains were sensitive to chloramphenicol (Chloromycetin), and the 35 that were tested for bacitracin were all sensitive to it. It is suggested that chloramphenicol be used to treat patients with penicillin-resistant micrococcal infections. The combination of antibiotics with a synergistic action may give even better results. The sensitivity of the bacteria to the antibiotics should always be tested before their administration.

 Fatigue: Symptom of Adrenal Dysfunction. M. R. Rivoire, J. Rivoire and M. J. Poujol.—p. 1431.

Transplantation of Kidney.—In a 16-year-old carpenter, a right nephrectomy was performed for injuries following a three story fall from a scaffolding. His postoperative condition appeared to be good, but there was total anuria. Six days after the accident, a diagnosis of aplasia of the left kidney was made and confirmed roentgenologically. The next day, the normal right kidney of the boy's mother was removed and embedded

in his external right iliac region. The graft was anastomosed to the stump of the ureter left after nephrectomy, and continuity was restored by means of a ureteral catheter that had been inserted before the intervention and that was now pushed up to the kidney pelvis. For 21 days after this operation, the transplanted kidney functioned excellently; then, abruptly, another period of total anuria began. This led to death in a convulsive state of azotemia 11 days later (exactly 40 days after excision of the original single kidney). The 21 day interval of normal functioning of the homograft before the onset of the anaphylactic reaction coincides with the time lapses experienced in other cases of renal transplantation in man and animals reported in the literature. This case differs from all previous ones, however, in that the close kinship of donor and recipient, and similarity in their blood types, establish unusually favorable conditions for the transplant. Other favorable factors were the lack of previous renal disease and of local complications and excretory dysfunction. During the time that the transplanted kidney was functioning, the process was normal with regard to diuresis, cytology of the urine, rate of voiding, urea concentrations of both blood and urine, and tubular resorption as evidenced by electrolyte excretion. Only three things are worthy of mention as possible warning signs: a slight, but regularly progressive, tendency toward elevation of the blood pressure, a progressive hypergammaglobulinemia, and a slight proteinuria appearing in the last few days before the unusually violent onset of the apoplectic phenomena involving the graft. The kidney became enormously enlarged within a matter of seconds, total anuria developed, and irreversible vascular, interstitial, glomerular, and tubular changes occurred. The exact mechanism of this attack is not known.

- *Wilson's Disease (Genealogical, Clinical, and Metabolic Investigations Affecting 60 Members of a Family). G. Heuyer, A. Baudouin, H. Azima, and others.—p. 165.
- Case of Hypertrophic Neuritis Accompanied by Hemispheric Degeneration and Malformations. I. Bertrand, S. Thieffry and E. Bargeton.—p. 182.
- Very Late Myelopathy Following an Odontoid Fracture with Atlanto-axoid Luxation. L. Barraquer-Bordas, L. Barraquer-Ferré, F. Duran and others.—p. 193.

Wilson's Disease (Hepatolenticular Degeneration).—The material for this study consisted of a 14-year-old girl with typical, fatal hepatolenticular degeneration and her entire family, comprising 63 members in four generations. The patient's illness, which began with choreic symptoms first noted in January, 1951, after an attack of influenza, progressed steadily until her death 23 months later. Treatment with dimercaprol [BAL] was tried without success. Investigation of the family showed that one of the patient's brothers had also died of typical hepatolenticular degeneration; another brother had died, while the family were refugees, of an unidentified fulminating disease that may have been an ascitic form of this condition; a sister, expatriated to Algeria, had died of a condition diagnosed as hepatic icterus that may have been hepatolenticular degeneration; and two infant siblings had died of meningitis and bronchopneumonia respectively. Seven living members of the family refused to participate in the study, and two had been lost sight of. Twenty-five others who were apparently in good health and fully cooperative were studied in respect to amino acid and copper metabolism. Determinations were made of the total copper, globulin copper, and total iron levels in the blood and of the copper and amino acids in the urine. The figures for total copper were above normal in two subjects and subnormal in three, but the variations were not pronounced enough to indicate a significant disturbance. Subnormal globulin copper levels were detected in six subjects. No significant disturbances were found in the amino acid or iron metabolism. Very few abnormalities were disclosed by the tests, but it must be remembered that none of the subjects studied had hepatolenticular degeneration. The clinical and biological symptoms characteristic of hepatolenticular degeneration all appeared concomitantly in the author's patient, supporting the belief that they must all be present if a diagnosis of typical hepatolenticular degeneration is to be maintained.

It may be that the disturbances in question each represent a distinct hereditary dysgenesis and that typical hepatolenticular degeneration occurs when these factors, appearing in combination in a single person, become operative under the stress of life.

- A Particular Case of Systemic Reticulohistiocytary Granuloma: Acute Aleukemic Hyperplastic Adenic-Splenic-Hepatomegalic Reticuloendotheliosis Involving Thymus, Peyer's Patches, Solitary Follicles, Lung, and Basilar Leptomeninges. A. Gentili and M. Lopez.—p. 1.
- *Injection of Gamma Globulin and Procaine into Aorta and Veins in Treatment of Acute Anterior Poliomyelitis. F. Ragazzini, M. Giusti, A. Pazzaglia and others.—p. 44.
- Salmonellosis in Picture of Infantile Diarrheas. W. Tangheroni.—p. 47.

Gamma Globulin and Procaine in Poliomyelitis.—Since May, 1951, the authors have been treating patients with poliomyelitis by injecting gamma globulin into the aorta and procaine into the veins. Their aim is to establish with the gamma globulin an intense passive immunization in the initial acute phase of the disease and with the procaine a protective action on the neurovascular apparatus during the same phase of the disease and a peripheral eutrophic action on the neurovascular apparatus during the phase of recovery and convalescence. They classify their patients as having severe cases when both legs are involved, very severe cases when there is bulbar localization and all four extremities are involved, moderate cases when more than one group of muscles is affected in one leg, and mild cases when only one group of muscles is affected. They inject from 4 to 14 cc. of gamma globulin into the aorta (sometimes with plasma) after an injection of from 5 to 10 cc. of procaine also into the aorta. This is repeated three or four times on the following days. Concurrent intravenous administration of procaine is carried out three to four times daily and is supplemented with antibiotics, vitamins B₁, C, and E. This therapy is continued for three or four 15 to 20 day courses. When injections into the aorta are too dangerous for patients in whom all the extremities are involved, the intravenous route alone is used; in mild cases the gamma globulin is injected intramuscularly. In few instances in which the authors injected small quantities of gamma globulin intrathecally, it was tolerated well, but the cellular reaction of the fluid was marked. Physical therapy with massage, galvanotherapy, occupational therapy, and sometimes application of appropriate orthopedic apparatus are used in some patients after the painful neuritic phase of the disease has passed. The authors treated 95 patients with poliomyelitis. The disease was very severe in 31 patients, severe in 24, moderate in 20, and mild in 20. A total of 51 injections into the aorta were given to 27; among these were 16 in whom all the extremities were involved. There were no side-effects. The results were considered optimal when there was 90 to 100% restoration of the muscle function, good with 70 to 90%, moderate with 50 to 70%, and poor with up to 25% restoration of the muscle function. The early results were optimal in 13 patients, 2 of whom had the very severe and two the severe form of the disease; good in 21 of whom 3 had the very severe and 10 the severe form; moderate in 30; and poor in 13. The condition remained unchanged in two patients in whom all the extremities were involved. Although a definitive statement is still premature, the results seem encouraging.

- New Treatments for Leukosis. J. Bernard and G. Deltour.—p. 3430.
- Initial Stage of Blood Coagulation. J. L. Beaumont, J. Caen and J. Bernard.—p. 3437.

Idiopathic Acute Thrombopenic Purpura.—The authors have seen 24 cases of acute thrombopenic purpura, among which 23 spontaneous remissions occurred. There was one death caused by cerebral hemorrhage. Duration of thrombopenia ranged

from five days to five months, but the average duration was about 30 days. The disease is not uncommon and occurs particularly in children and with equal frequency in both sexes. It is characterized by certain hemorrhages, purpura, frequently epistaxis, sometimes bleeding intrabuccal bullae, and hematuria, accompanied by a typical thrombopenia. The evolution of the disease is rapid, as is its disappearance which is usually definitive. The etiology and physiopathology of the syndrome are unknown. Attempts to isolate allergic factors or antiplatelet substances were unsuccessful in this series of cases. Differential diagnosis between chronic thrombopenic purpura of the hematogenous type and acute thrombopenic purpura is often difficult, but important, in view of the different therapies indicated. Blood transfusion is the principal treatment in acute purpura. Splenectomy, which is usually necessary in chronic purpura, is rarely indicated for the acute variety. When thrombopenic purpura has appeared only recently, intervention should, if possible, be delayed until after at least six months, and sometimes as long as a year, on the theory that the disease may be acute.

Pigmentation of Lips and Buccal Mucosa Associated with Intestinal Polyposis.—Trengove Jones presents the histories of four patients in whom perioral and buccal pigmentation concurred with intestinal polyposis. The pigmentation conformed with Siemen's description of "ephelides inversae." The pigment occurred on the mucosa of the lips and around the mouth, areas that are usually immune even in freckled subjects. The pigmentation was punctate in distribution and varied from black to brown. The marks could not be obliterated by lip-stick. The skin lesions had been present as long as the patients could remember. In only one patient was it possible to establish beyond doubt that the lesions had been present at birth. The polyps in all these patients were pedunculated and occurred in the small bowel. They all presented as intussusceptions. In every case only one polyp was found. The histology was consistently that of a benign adenomatous polyp, and in only one case was pigment detected. In only one case was it possible to establish any relevant family history. Two of this patient's brothers had the typical pigmentation around the lips and mouth but by middle life had shown no symptoms or signs that could be attributed to polyposis. There is, however, presumptive evidence in a review of all recorded cases that the syndrome is familial and is transmitted as a dominant Mendelian characteristic. The association of this pigmentation with intestinal polyposis was first observed by Peutz in 1921 and is also known as the syndrome of Peutz.

Present Orientation of Surgery for Pulmonary Tuberculosis in United States. E. Forster.—p. 511.

Some Indications and Contraindications in Surgical Treatment of Pulmonary Tuberculosis. P. Oudet.—p. 515.

Appraisal of BCG Vaccine.—The author considers three questions: the present importance of vaccination of any kind against tuberculosis (in view of the rapidly declining mortality rate), the disadvantages of BCG in particular, and the over-all results of immunization by BCG vaccine in the past. The point made

regarding the first question is that the decreasing mortality is a reflection only of modern therapy of tuberculosis and has not been accompanied by a corresponding decrease in morbidity. Immunization prior to onset of the disease is still of vital importance, especially considering the long, incapacitating, and expensive character of the treatment. BCG has proved effective for this immunization during the 30 years of its use. Its side-effects can be disturbing, especially in the newborn, but they are not serious or permanent. Care must be exercised so that vaccination is not done on those persons strongly exposed to the disease. The enormous amount of statistical material that exists, however, is overwhelmingly in favor of the efficacy of BCG vaccine; and the author sees no reason to discredit the old saying, "Prevention is better than cure."

*Fatal Poisoning from Use of Hydrochloric Acid in Confined Space. E. Thiele.—p. 146.

Determination of Porphyrin in Urine of Workers Exposed to Lead. H. Groetschel.—p. 146.

Dangers in Exposure to β -Dimethylaminoethylchloride or β -Diethylaminoethylchloride.—Klavis points out that β -dimethylaminoethylchloride as well as β -diethylaminoethylchloride are used in the synthesis of antihistaminics and various muscular relaxants. Although tissue changes had been known to be produced by direct contact with diethylaminoethylchloride, there was no record of detrimental effects having been produced by dimethylaminoethylchloride. When, however, 10 laboratory workers showed signs of irritation on the conjunctivas and the nasal mucous membranes, as well as visual disturbances, further investigations seemed necessary. An accident helped to clarify the causal connection. Protective goggles had been unknowingly allowed to come in contact with dimethylaminoethylchloride, and especially severe irritation and visual disturbances developed in the laboratory worker who wore these goggles. It was surprising that the catarrhal symptoms characteristic of diethylaminoethylchloride were less prominent when there was exposure to dimethylaminoethylchloride. The occasional catarrhs were slight and did not noticeably impair physical performance; however, there were complaints about photophobia, lacrimation, and, more rarely, about slight respiratory disturbances. Reduction in the accommodative capacity with pupillary involvement deserves special mention; its severity, like that of the clinical course, is dependent on the concentration and length of exposure to the harmful agent. Ophthalmologic examination of these laboratory workers disclosed in all excessive hyperopia that made all close work, particularly reading, very difficult. In one laboratory worker who had been exposed for a short time to a high concentration of dimethylaminoethylchloride, complete ophthalmoplegia interna (with maximal dilatation of pupils and complete paralysis of accommodation) and rotatory nystagmus developed. Work had to be interrupted for two weeks, and during this time normal accommodative capacity was restored.

Fatal Poisoning from Use of Hydrochloric Acid in a Confined Space.—A suction pipe (diameter 4 in. [10.16 cm.]; length 100 m.) between the well and the cooling system of a brewery was to be cleaned with a solution (30%) of hydrochloric acid. The pipe had been filled with 350 liters of the fluid, and after it had been in the pipe for about 30 minutes it was withdrawn in buckets at the well end of the pipe by a man who stood on a ladder about 3 m. below the top of the well. The man ascended the ladder behind the bucket, which was drawn up by a cable drum. He collapsed and fell in while sitting at the edge of the well trying to get fresh air. His co-workers brought him up immediately, and he regained consciousness. After a physician arrived about 2 hours later, he was at once taken to the hospital where he died shortly afterward. Necropsy revealed that death was due to massive pulmonary edema. There were indications that the acid solution had emitted vapors.

BOOK REVIEWS

Modern Trends in Urology. Edited by E. W. Riches, M.C., M.S., F.R.C.S., President, British Association of Urological Surgeons, London. With foreword by Lord Webb-Johnson, K.C.V.O., C.B.E., D.S.O. Cloth. \$12.50. Pp. 476, with 215 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd Street, New York 16, 1953.

This volume consists of 38 chapters written by distinguished specialists, each of whom is well qualified to discuss the subject to which he has been assigned. The book is not a stereotyped text but deals with most urologic entities emphasizing recent trends and advances in therapy. Appropriate medical and surgical treatment in urology depends on careful evaluation of the associated bacteriological and pathological conditions. Regular visits to the pathologist as a helpful aid in solving some of the difficult problems are suggested. The indiscriminate use of antibiotics without bacteriological identification of causative organisms is condemned, as this incurs the risk of producing resistant strains of bacteria. The reader is reminded that older and simpler remedies such as methenamine mandelate (Mandelamine) and the sulfonamides are still effective.

An especially valuable section is the complete, concise presentation of the problem of the obstructive prostate, both benign and malignant. All surgical procedures are clearly presented and neatly illustrated. The indications, shortcomings, and complications of each technique are clearly pointed out. The diagnosis and treatment of bladder and renal tumors conforms to the modern thinking with regard to these lesions and should be most helpful to graduate and undergraduate students. In the treatment of renal tumors, nephrectomy and radiation are favored. Chapter 4 deals with translumbar aortography, but the dangers of this procedure are barely mentioned. Case reports include pyelograms, aortograms, and photographs of pathological specimens that are well reproduced and correlated. The volume contains little information on scrotal lesions. The inclusion of a short treatise on testicular tumors and their management would help to round out the discussion of important urologic diseases. On the other hand, chapter 31 concerns the reconstruction of the male urethra in strictures with the Dennis-Browne technique, which is a major undertaking and perhaps rarely indicated.

The need to regard urology as a specialty is stressed. Special delicate and expensive equipment is particularly essential in carrying out the endoscopic procedures. "Experience and skill in general surgery are of fundamental importance to the would-be urologist and before exclusive specialization in urology is allowed a trainee should have reached the grade of a senior registrar in general surgery, and have had outpatient urological experience." The problem of undergraduate urologic hospital teaching is well treated, and factors modifying specialization, such as the necessity of surgeon-urologists in smaller hospitals, are included in the discussion. The fact that at present there is no endowed chair of urology in any university in Great Britain is lamented, but hopes are high for its realization in the near future. The volume is printed on good paper, and the type is pleasing. Urologists and general surgeons will find this book a help in the study and review of urologic diseases. The volume reflects the comprehensive knowledge and broad experience of the authors.

Méningite tuberculeuse et tuberculose miliaire de l'enfant: Leur traitement. Par Robert Debré, professeur à la Faculté de médecine de Paris, et H. E. Brissaud. Avec la collaboration de J. Raynaud, et al. Paper. 5000 francs. Pp. 632, with 237 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris, 6e, 1953.

This monograph contains an analysis and synthesis of the authors' experiences based on 644 patients entering their service between January, 1947, and October, 1952. In August, 1952, 286 (52%) were alive. The major consideration was to study

tuberculous meningitis in the infant and its treatment from the point of view of clinical forms, biological examination, and anatomic lesions. Much of the information is not new, but the changes due to treatment are new in transforming the course of the disease. The symptoms are rapidly modified by treatment; intracranial hypertension signs disperse, consciousness returns, temperature drops, and the course becomes favorable unless the causative organisms are resistant. The subacute form thus may become chronic. Diverse complications were noted. The subject is covered in detail with the aid of many illustrations. The etiology and the initial period of tuberculous meningitis, the principle forms of evolution, complications, clinical forms, cerebrospinal fluid, bacteriology, the use of electroencephalography, ophthalmic lesions, evolution of lesions, prognosis, differential diagnosis, treatment, and military tuberculous meningitis are discussed. The author concludes that (1) tuberculous meningitis results from a massive general familial exposure, frequently to streptomycin-resistant bacilli in which case it progresses rapidly; (2) bovine transmission is exceptional; (3) there is 1 case of meningitis to 300 primary infections; (4) the risk of meningeal complication is great in the presence of military involvement of the choroid; (5) exogenous reinfection plays no role in producing meningitis; (6) heredity likewise plays no role; (7) Kernig's sign and nuchal rigidity are frequently absent; (8) complications are numerous; (9) alterations in cerebrospinal fluid are frequently the only diagnostic signs; (10) the organization of special laboratories is essential to diagnosis; (11) circulatory disturbances and changes in the optic disk are important; (12) the mortality is 70% for infants of 1 year decreasing to 34% at 6 years; (13) the mortality increases from 35% to 89% if the tubercle bacilli are resistant; (14) antituberculosis drugs have greatly improved the prognosis for patients with military tuberculosis; and (15) military tuberculosis complicated by meningitis is severest. This accumulation of data on tuberculous meningitis, well presented in French, should be valuable to all conversant with French and interested in the treatment of tuberculosis in infants.

Facial Deformities and Plastic Surgery: A Psychosocial Study. By Frances Cooke MacGregor, M.A., et al. Publication number 174, American Lecture Series, monograph published jointly in Bannertown Division of American Lectures in Psychology and American Lectures in Psychiatry. Psychology series edited by Molly Harrower, Ph.D. Psychiatry series edited by Roy R. Grinker, M.D., Director, Institute for Psychosomatic and Psychiatric Research and Training, Michael Reese Hospital, Chicago. Cloth. \$5.75. Pp. 230, with illustrations. Charles C. Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad Street, Oxford, England; Ryerson Press, 299 Queen Street, W., Toronto 2B, 1953.

This book is the product of a research project made possible by a grant from the National Institute of Mental Health, U. S. Public Health Service. It discusses in detail typical case histories and the psychosocial, psychological, and psychiatric aspects of these and other representative problems. The elementary details included will bore a thoroughly experienced plastic surgeon but will be attractive to social and educational workers primarily concerned with personal and family problems. The case histories remind one of involved reports of "do-gooders" whose primary enthusiasm exceeds their insight into the unimportance of irrelevant details. The treatise will, however, increase the readers' perspective into problems of deformity and disfigurement. Younger surgeons uncertain whether to enter the field of reconstructive surgery will be helped in their deliberations by this study; those who have recently entered the specialty will acquire insight that time and experience will confirm.

All who work in this field must be perpetually aware of the mental components of visible structural impairment. Only then can the reaction of patients to disfigurement and its surgical implications be appraised and prognosis wisely guarded. All of these problems, though involved, are real; some patients actually have mental troubles that far exceed the physical. Intimate

analysis requires more time than the surgeons can give and therefore belongs to workers whose primary interests are in the departments of sociology and psychology. The book is easy to read and is not designed to convey any technical or scientific treatment of the field of plastic and reconstructive surgery. Covering an essential ancillary field, however, it will serve a useful purpose in furthering the education of our fellow workers.

Physiological Cardiology. By Arthur Ruskin, M.D., F.A.C.P., Associate Professor of Internal Medicine, University of Texas—Medical Branch, Galveston, Texas. Publication number 184, American Lecture Series, monograph in Bannerstone Division of American Lectures in Physiology. Edited by Robert F. Pitts, M.D., Ph.D., Professor of Physiology and Biophysics, Cornell University Medical College, New York. Cloth. \$8. Pp. 370, with 9 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This volume tries to encompass the wide field of cardiac physiology and its clinical implications in a mere 318 pages. This results necessarily in a rather staccato style of presentation and the author cannot even attempt to go into detail or state the controversial viewpoints regarding many of the subjects mentioned. The brevity and condensed form of this book may, however, be of value to the student or the candidate for a specialty board examination. The typography of the book is excellent, and the bibliography gives the most important sources of general information in the field. The few illustrations are well selected.

Preparation for Medical Education in the Liberal Arts College: The Report of the Subcommittee on Preprofessional Education of the Survey of Medical Education. By Aura E. Severinghaus, Ph.D., Harry J. Carman, Ph.D., and William E. Cadbury, Jr., Ph.D. Cloth. \$4.50. Pp. 400. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, 1953.

More than a hundred liberal arts colleges were comprehensively studied over a two year period by the Subcommittee on Preprofessional Education in their efforts to determine the educational opportunities that these institutions offered to pre-medical students. Their report is well written and contains a wealth of carefully considered and important information concerning the preparation of college students for later professional training in medicine. Following a description of the organization, objectives, strategy, and technique of the survey, the report begins with an analysis of the premedical student. This is followed by an excellent presentation of the advisory system as currently found in our institutions of higher education and highlights the value of college advisory systems when they are worthy of such designation. Certainly one of the functions of our institutions of higher education should be to help young persons find and correctly orient themselves in regard to their future life work, and the role of good advisory systems in accomplishing this function is well presented. The need for effective liaison between the colleges and medical schools is clearly stated, and the reasons for the success or failure of satisfactory interchange of knowledge between them are indicated.

Throughout the volume, the value of a broad cultural background for future professional training is stressed and it is emphasized that: "It is more important that a student's life be made meaningful in medical school, and afterward, than that it should be made easy." Efforts are made to describe a balanced education and to state the relative merits of the several disciplines as a background preparation for medical education. Major courses and the importance of the culminating year before admission to medical school are then described, and this is followed by an account of several stimulating ventures in college education now being conducted in different parts of the country. The teacher and his methods and the challenges confronting teachers as well as the types of teaching failure and their probable causes and remedies constitutes a most valuable chapter of the report. Influences outside the classroom, personal and social responsibilities, and trends and outlook are dealt with in the closing chapters of the volume with the happy note that the "outlook is good because so many are in quest of the best."

About 150 pages of appendix material are included, much of which is highly significant to all educators and which should

be read in full. The entire volume represents a worthy analysis of the problems confronting educators in preparing students for professional study. It is a notable contribution that deserves careful reading on the part of all who are engaged in teaching and administration in liberal arts colleges as well as in professional schools regardless of their area of discipline. It is to be hoped that application of the principles set forth in this volume will help to make the student's life more meaningful.

Symphathikus Chirurgie. Von Prof. Dr. Paul Sunder-Plassmann, Direktor der chirurgischen Klinik und Poliklinik der Universität Münster (Westf.). Cloth. 54 marks. Pp. 162, with 146 illustrations. Georg Thieme, Diemers-haldenstrasse 47, (14a) Stuttgart O; [agents for U. S. A., Grune & Stratton, Inc., 381 Fourth Ave., New York 16], 1953.

This is a scholarly approach to the subject of sympathetic surgery. Although thoroughly conversant with the existing literature, Professor Sunder-Plassmann has gathered the bulk of the material for this monograph from his personal experiences. This makes the book particularly valuable. The author calls attention to the fact that it is the general practitioner who sees the sympathetic syndrome first and that he has forced the specialists in this field to attempt to provide some specific forms of therapy and to establish the indications for their use. The discussions that emanate from various clinics regarding the value of stellate blocks, sympathetic resections, ganglionectomies, and similar procedures are not answered in a definitive manner. In fact the author states that, in most of these cases, such an answer cannot yet be presented. He emphasizes, however, that such "violent discussions" are well worth while as a stimulus to coordinating and correlating the available material.

In this day, with the trend toward statistical analysis, it is refreshing to find an intelligently written text that plays down statistics. The author reports on 510 sympathetic surgical procedures, only 7 of which were stellate ganglion resections. It is to his credit that in his series only two patients died. Rather than listing various indications and contraindications he discusses the conscientious indications for the various procedures. The lack of statistical data in the book is not due to the loss of Professor Sunder-Plassmann's personal figures in a bombing in the last war but due to his belief that statistics, numbers, and technique play the least important roles in the approach to this subject. His *sine qua non* for a procedure is based on knowledge of anatomy, physiology, and pathology, to be sure, but these subjects do not supersede the importance of judgment. Although he attaches little importance to surgical exhibitionism, he does not belittle surgical dexterity. He has brought to the fore the significance of psychosomatic medicine, which, he believes, should fall into the realm of the average general surgeon. The text has been properly embellished by good illustrations, fine microphotography, and ample case presentations. The close coordination between artist and author is readily discernible as one reviews this work. Although no specific answers can be drawn from this monograph, it will prove stimulating as well as helpful to those interested in the subject. A rather thorough reading knowledge of German would be required to appreciate fully the text.

Handbook of Acoustic Noise Control. Volume II: Noise and Man. By Walter A. Rosenblith, Kenneth N. Stevens, and staff of Bolt, Beranek, and Newman. WADC technical report 52-204. Aero Medical Laboratory contract no. AF 33(038)-20572, RDO no. 695-63. Paper. Pp. 262, with illustrations. Wright Air Development Center, Air Research and Development Command, United States Air Force, Wright-Patterson Air Force Base, Ohio, 1953.

This handbook was written for the benefit of all those who have the responsibility of "doing something about noise." This includes the doctor, the industrial hygienist, the safety engineer, the architect, the administrator, the economist, the legislator, and many others. The problems cut across all administrative boundaries, professional groupings, and academic disciplines. The handbook is addressed to just such a general audience, centering on the planners and the engineers, and it summarizes in effective form and language, with the aid of well-selected charts, graphs, and tables, the present state of knowledge of the biological and psychological effects of noise on man. There have been important additions both to techniques and to knowl-

edge in these areas in the last few years, and nowhere else is there as good a compilation of this information or as good a selected bibliography. The doctor who is interested in industrial medicine and even the specialist in otology will profit from the chapter entitled "Basic Bio and Psychoacoustic Data," with its excellent subsections on audiometry and speech communication. It will be interesting to those who know these subjects well from the clinical point of view to read this exposition of the psychoacoustic principles of audiometry addressed to readers with an engineering or administrative background. Here the medical man will learn something of the points of view of both the engineer and the experimental psychologist.

The perspective in relation to such problems as human response criteria for noise control and the effects of noise on human behavior is excellent. Many paragraphs are devoted to pointing out clearly and emphatically the complexities of both of these problems, the difficulties of obtaining numerical data, and the necessity for reaching common understandings on certain original definitions and assumptions before any firm rules can be laid down. Nevertheless, in spite of all the uncertainties, the authors give their best conjectures as to certain tentative criteria. For the problem of interference by noise with communication by speech, assumptions and even rules can be made with fair confidence. The criteria for prevention of hearing loss, however, must have been drawn up with fear and trembling. The limitations of these criteria are many and they are clearly stated. The doctor or anyone else interested in problems of loud noise would do well to obtain a copy of the report for this section alone. This report was prepared by the Air Force for use by supporting industry. It is available to all through the Office of Technical Services, Department of Commerce, Washington 25, D. C., and should find wide distribution.

Resuscitation of the Newborn. By Joseph D. Russ, M.D., F.A.A.P., Assistant Professor of Pediatrics, Tulane University School of Medicine, New Orleans. Publication number 193, American Lecture Series, monograph in American Lectures in Anesthesiology. Edited by John Adriani, M.D., Director, Department of Anesthesia, Charity Hospital, New Orleans. Cloth, \$2.50. Pp. 55, with 7 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St. W., Toronto 2B, 1953.

Because mortality in infants on the first day of life is still much higher than at any other period in infancy, it is important for all physicians to be aware of the causes for asphyxia and proper methods to employ for resuscitation of the newborn infant. As used in this book, the term asphyxia refers to failure of respiration. The importance of establishing respiration within 30 seconds after severance of the cord is pointed out because of the irreversible damage to the cerebral cortex that may occur due to insufficient oxygenation of the blood. The clinical factors contributing to asphyxia, methods of resuscitation, and after-effects of asphyxia are described. Treatment consists chiefly of supplying immediate warmth with a minimum of handling; clear, open airways; and oxygenation of the blood. The importance of the tracheal catheter is stressed. The application of the principles presented in this book should aid in reducing the unnecessarily high mortality rates of the first days of life.

Einführung in die Augenheilkunde. Von Prof. Dr. med. J. A. Jaensch, Obermedizinalrat und Chefarzt der städtischen Augenklinik zu Essen. Second edition. Cloth. 22 marks. Pp. 244, with 197 illustrations. Georg Thieme, Diemershaldenstrasse 47, (14a) Stuttgart O; Agents for U. S. A., Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

The pattern of this abbreviated textbook of ophthalmology, intended for the use of German medical students and general practitioners, follows that of American books by May-Perera, Gifford-Adler, Town, Goar, and Hughes. There is a logical, systematic, and concise but sufficiently comprehensive exposition of the ophthalmologic disorders most frequently encountered. Surgery is referred to but briefly. Many of the better illustrations are reproduced from Thiel's atlas. This volume should fill an important place in medical education in German-speaking countries but, because of language difficulties and the abundance of similar books in English, there will be little demand for it in the United States.

Design and Construction of General Hospitals. By U. S. Department of Health, Education and Welfare, Public Health Service. Cloth. \$12. Pp. 214, with illustrations. F. W. Dodge Corp., 119 West 40th Street, New York 18; in collaboration with Modern Hospital Publishing Co., 919 N. Michigan Ave., Chicago 11, 1953.

Although the perfect hospital never has been constructed and probably never will be, the use of this volume as a reference and guide will prevent many of the errors that show up after completion. It is refreshing to note that the authors admit that "each hospital is a problem unto itself." The section on construction and design starts with a consideration of how to select the site and progresses through every department and all facilities and factors that influence construction. The traffic flow charts and area allotments for each department in the hospital, included in this section, are valuable aids. The section entitled "Schematic Plans of General Hospitals" includes units from an 8-bed community clinic with a nursing division to a 200-bed hospital for an urban district, this being in line with the "Coordinated Hospital System," a plan generally accepted as providing the public with the most economical health service. Useful charts on equipment costs and floor plans and equipment and supply lists for hospitals containing from 50 to 200 beds are included. The book is chiefly for those whose responsibility it is to build new hospitals, but it can well serve as a guide and reference in remodeling and enlarging existing facilities. Students of hospital administration will find much of value in this reference book.

Wonders of Modern Medicine. By Steven M. Spencer. Foreword by George F. Lull, M.D., Secretary and General Manager, American Medical Association. Cloth. \$4. Pp. 276. McGraw-Hill Book Company, Inc., 330 W. 42nd Street, New York 36; 95 Farringdon Street, London, E.C.4, 1953.

The author of this book, formerly a president of the National Association of Science Writers and a student of physiology and other medical subjects at Harvard University under a Niemann Fellowship in journalism, has written a convincing, informative, and exciting account of the advances made in medicine during the past decade or so. Today the best science writers specializing in medical subjects are conscientious reporters who do a great deal of painstaking research before translating medical information into readable form. As a group these writers are aware of their responsibility to lay readers, and they guard against premature and overoptimistic announcements that tend to arouse false hopes among both the general public and physicians. The book deals with such timely medical topics as surgery of the heart, arteriosclerosis, cancer, radioactive isotopes, antibiotics, gamma globulin, glaucoma, arthritis, diabetes, and epilepsy. To learn the successes, disappointments, and struggles that have characterized medical science in recent years, the general reader would do well to read this fascinating book in its entirety.

Design for Decision. By Irwin D. J. Bross. Cloth. \$4.25. Pp. 276, with illustrations. The Macmillan Company, 60 Fifth Avenue, New York 11, 1953.

This book discusses the theory of probability and statistics in an informal manner, with much incidental philosophizing, a liberal use of the first and second personal pronouns, and the irreducible minimum of numbers and symbols. Unfortunately, the symbols cannot always be those familiar to the student who has had only high school algebra, and the style cannot appeal to every reader. However, the content of the book is important because it includes some ideas that have been undergoing rapid development in recent years, especially the idea of sequential analysis. This is the body of principles underlying the probability of successive events and specifying the conclusions justified by samples drawn in succession from the same lot of material. While this is of particular interest in industrial quality control, it must also have its applications in medicine. For instance, the metropolitan citizen's daily rides to work may be regarded as a sequential sampling of the bacterial flora of the subway system. There should be further elaboration of the medical aspects of this problem, a clearer statement of Bayes' rule, and some warning when words like "order" (page 77) are to be used in a special sense. With attention to some of these points a future revision of this commendable work may have greater appeal for the medical reader.

QUERIES AND MINOR NOTES

THE COMMON COLD

TO THE EDITOR:—I will appreciate information concerning the efficacy of corticotropin (ACTH) and cortisone, with or without other adrenal hormones, in the abortion of incipient common colds. If it can be used with advantage, please indicate the dosages and adjuvant medications such as antihistaminics. What are the newest developments in prophylaxis and treatment of the common cold?

M.D., New York.

This inquiry was referred to three consultants, whose respective replies follow.—ED.

ANSWER.—Although a number of vaccines have been developed for prevention of the common cold, none has received general acceptance. Infected tonsils or facial sinuses may play some part in those who are subject to frequent colds. Allergic conditions may also deserve attention. There is no established method for prophylaxis. The "orthodox" treatment of the common cold is much the same now as in the past. Nevertheless a sulfonamide or more likely an antibiotic is likely to be prescribed and in some instances may be of value. It is a good plan to obtain a culture from the nose and throat to determine if organisms other than a virus are present.

ANSWER.—No drug or combination of drugs acts specifically in the prophylaxis or treatment of the common cold. Many nostrums and remedies have been advocated for either or both of these purposes, such as alkalis, vitamins, laxatives, antihistaminic drugs, and many others; none of them can be shown to be effective in controlled studies. The physician can often obtain symptomatic relief for his patients by prescribing aspirin, codeine, atropine, papaverine, or combinations of these drugs.

ANSWER.—No clinical report is available that recommends the use of corticotropin (ACTH) or cortisone for the treatment of the so-called common cold. On the basis of available studies with these compounds in the management of most other bacterial and viral infections, the use of corticotropin or cortisone is contraindicated in the treatment of incipient common cold. Their administration may interfere with normal immunologic processes of the body and thus may result in depression of the usual salutary antibody production.

TENOSYNOVITIS OF FINGER

TO THE EDITOR:—A man, aged 30, suffers from tenosynovitis of the right middle finger, with crepitus and slight ganglion formation at the metacarpophalangeal joint. He also has peptic ulcer. His general physical condition is good. Would he be benefited by cortisone by mouth? Would hydrocortisone (Hydrocortone) by injection into the hand be of any help? What is the best treatment for this condition?

Harry Hallarman, M.D., New York.

ANSWER.—From the description it appears that this patient has a mild chronic tenosynovitis. The hormones by mouth or local injection probably would be of no value, and might be dangerous in the presence of a known peptic ulcer. The best treatment is difficult to assess because it is not known whether this is a specific tuberculous infection or a chronic nonspecific manifestation. At times complete immobilization of the hand in the position of function will improve this condition, but eventually in most cases surgical excision of the involved tendon sheath is done.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

BLOOD UREA AFTER NEPHRECTOMY

TO THE EDITOR:—For two years I have taken care of a patient, 60 years of age, who had a nephrectomy 30 years ago for tuberculosis. The left kidney is radiologically normal, the diet is quite moderate, and the blood urea averages, over two years, 55 to 60 mg. per 100 cc. by xanthidrol method. The latest value was 65 mg. by the hypobromite method. Is it known that the blood level of urea may be physiologically higher with one kidney than with both?

M.D., Paris, France.

ANSWER.—The inquirer is referred to an article by Ellis and Weiss (*Am. J. M. Sc.* 186:242, 1933) for blood urea and urea clearance findings in persons who have had nephrectomy and to a report by Addis and co-workers (*Arch. Int. Med.* 34:243, 1924) for the same determination in rabbits that have had unilateral nephrectomy. It has been established that unilateral nephrectomy does not result in an abnormal increase in the blood urea, provided the remaining kidney is normal. Occasionally one may encounter a rise in the blood urea immediately after nephrectomy, if the circumstances of dehydration and excessive protein catabolism are present. An abnormally high blood urea level persisting after nephrectomy indicates that the remaining renal tissue is damaged and cannot maintain homeostasis. Normal blood urea levels are 25 to 30 mg. per 100 cc. by the xanthidrol reaction by Goldbaum. The fact that the patient mentioned has a blood urea level of 55 to 60 mg. per 100 cc. implies that his remaining kidney is in a deteriorated state despite normal urograms. A normal pyelogram does not necessarily rule out renal disease. Not infrequently one observes normal pyelograms in patients with glomerulotubular nephritis or arteriosclerotic nephropathy. To determine the functional status of a kidney, it is necessary to employ one or more of the quantitative tests. The methods employed most frequently in the clinical practice of medicine are the urea clearance, creatinine clearance, and phenol-sulfonphthalein excretion tests. After unilateral nephrectomy and if the remaining kidney is normal, the urea clearance will be eventually about 70 to 80% of normal.

PRURITUS ANI

TO THE EDITOR:—A man, aged 68, had suffered for five months from pruritus ani. Local treatment by a proctologist did not bring relief. The history gave one clue: A fat poor diet had been continued for years with an excessive intake of brewers' yeast (about 10 teaspoonfuls daily of the powder). Supposing the yeast had a deleterious effect on the intestinal flora, similar to that of chlortetracycline (Aureomycin), I advised discontinuing use of yeast and to substitute once weekly injections of vitamin B₁₂ intramuscularly in doses of 30 mcg.

M.D., New Jersey.

ANSWER.—It is assumed that in the course of this patient's laboratory studies, intestinal infestation, particularly with regard to *Enterobius vermicularis*, was excluded. No reports were found of studies indicating a deviation from normal of the intestinal flora as a result of ingestion of brewer's yeast. It is well established that thiamine frequently increases intestinal motility. Pruritus may result from unattenuated pancreatic enzymes reaching the perianal mucosa. This is a common occurrence following any diarrhea of long standing. Has the physician investigated the possibility of achlorhydria as a cause of increased motility of the intestinal tract? This may result in subsequent pruritus ani. Elixir of Rubratorn (containing vitamin B₁₂, folic acid, and ferric ammonium citrate), 2 drams (8 cc.) four times daily, should be given the patient to relieve his pruritus. There should be a more detailed dietary history, followed by an attempt at normalizing the patient's dietary intake, supplemented if necessary, by a multivitamin preparation orally.

TETANY

TO THE EDITOR:—A woman, aged 62, has been suffering with tetany for 10 months that is apparently due to nonfunctioning parathyroid glands. Nothing does any good except calcium gluconate, 10 to 20 cc. intravenously daily, which she has received for 10 months. The veins are about destroyed and are very hard to enter. Can you suggest anything she could take by mouth or intramuscularly?

Merle A. Place, M.D., Hornell, N. Y.

ANSWER.—The therapy of tetany depends on its etiology. If it is due to hypocalcemia in association with hypoparathyroidism, pseudohypoparathyroidism, or renal insufficiency, it will respond to the following preparations, all given orally: vitamin D₂ in doses of 50,000 to 400,000 units a day, or dihydrotachysterol in doses of 1 to 3 cc. daily, along with 10 cc. of aluminum hydroxide with each meal and calcium gluconate, 1 to 2 teaspoonsful (4 to 8 cc.) three times daily. In addition, in renal insufficiency the acidosis should be controlled by the administration of base, such as sodium citrate. In hypoparathyroidism the problem of the use of calciferol or dihydrotachysterol is not so much prevention of tetany as ascertaining the dose required to maintain the serum calcium at or just below a normal level, rather than at an abnormally high level. This regulation is best managed with the aid of the Sulkowitch test for urinary calcium. It is generally advisable to utilize a diet high in calcium and low in phosphates, at least at the initiation of therapy. Parathyroid extracts yield diminishing effects with time, owing to antibody formation.

If the tetany is due to hypocalcemia associated with steatorrhea, dihydrotachysterol may not be effective since it is prepared in an oily vehicle and thus may not be absorbed. In addition, the formation of calcium soaps within the intestinal tract may markedly limit the availability of calcium for absorption. These factors may well explain the problem of control of tetany in the patient described above.

Nevertheless, the combination of vitamin D₂ and calcium gluconate or chloride in the manner indicated above is effective in the control of hypocalcemic tetany due to steatorrhea. There are available preparations of vitamin D₂ for intramuscular use, but they are very rarely necessary. It is worthy of note that "latent steatorrhea" has been described in which hypocalcemic tetany due to vitamin D lack may occur without gross changes in the stool (Cameron, D. G.; Bensley, E. H., and Wood, P.: *Ann. Int. Med.* 37:553 [Sept.] 1952). The possibility that the tetany may not be hypocalcemic but due to the hyperventilation syndrome or the ingestion of excessive alkali should be ruled out. It should not be necessary to administer calcium intravenously for an extended time.

FIRST AID EQUIPMENT

TO THE EDITOR:—I have been asked to make a list of supplies that should be kept in a first aid room for treating injuries due to falls on the ice in playing hockey or figure skating. I have done very little accident work for many years and wonder just what is considered the proper equipment to have on hand in order to get the patient to the hospital in good condition.

M.D., Montana.

ANSWER.—Assuming that a physician will be available to use the equipment, the following list is believed to include the most essential items: 1. For combatting shock: blankets, hot water bottles, aromatic spirits of ammonia, and meperidine (Demerol) or morphine. 2. For immobilizing injured part: tongue blades, basswood splints, wire ladder splints, hinged Thomas arm and leg splints with foot brace and support attachments, roller bandages (both muslin and gauze), safety pins, adhesive tape, arm slings, felt padding, and sand bags. 3. For control of hemorrhage: tourniquets, sterile 4 by 4 in. gauze dressings, and pressure bandages. 4. For associated wounds: 70% alcohol, tincture of thimerosal, safety razor, soap, suture materials, absorbent cotton, bandage scissors, and knives. 5. Miscellaneous items: folding litter, wheel chair, and crutches. In your particular situation there may be items not listed here that you will want to include, but this list covers the main essential items.

CHEST PAIN FOLLOWING INTRAVENOUS INJECTIONS

TO THE EDITOR:—Sometimes intravenous injection of, for example, iron, calcium, or vitamin C preparations cause angina-like pain for a few moments even in young patients with clinically normal hearts and even if the injections are given slowly. Is this a symptom of coronary sclerosis?

Naguib Habib, M.D., Giza, Egypt.

ANSWER.—Chest pain following an intravenous injection may occur as a consequence of generalized vasodilatation induced by the drug injected, resulting in a fall in systemic blood pressure and a state of transient coronary insufficiency. True angina occurs in this manner only in patients with abnormal coronary circulation in whom the ability to adjust readily to changes in pressure and flow is impaired. A second mechanism, and one that accounts for most reactions to intravenous injections, is the occurrence of vasovagal reactions due to irritation of medium-sized blood vessels along the course of the venipuncture. Such stimulation is followed by diaphoresis, cold sensations, dizziness or syncope, and a transient sense of vague substernal discomfort or mild oppression. Such chest pain rarely has the character of angina. Reactions of this kind may attend either venipuncture or arterial puncture and are not indicative of coronary disease. Calcium and iron preparations are intense local irritants and, it is for this reason, rather than because of contamination of such solutions, that vasovagal reactions are seen. In the sensitive patient, prior sedation as well as slow injection is helpful. Saccharated iron is notorious for causing reactions, and it should be emphasized that there are very few legitimate indications for giving iron intravenously.

COLOR BLINDNESS IN PROSPECTIVE STUDENTS

TO THE EDITOR:—Is it fair to refuse college students admission to schools of engineering, medicine, science, or agriculture because they are partially color blind?

Yung-chen Shih, M.D., Formosa, China.

This inquiry was referred to two consultants, whose respective replies follow.—ED.

ANSWER.—Partial color blindness does not seriously hinder the attainment of scientific achievement and high degrees of success in the activities mentioned. To refuse the admission to these fields of partially color blind students would be an injustice. Students with high degrees of color blindness may find themselves handicapped in some particular projects, but the fields of activity are wide and offer attractive prospects for visually handicapped students who are otherwise well qualified.

ANSWER.—A student should not be denied the opportunity to study medicine merely on the basis of partial color blindness. Although in certain fields of medicine a color-blind physician would be somewhat handicapped, the extent to which such persons are able to compensate is remarkable. One of the better medical schools in the United States a few years ago had four major department heads who were partially color blind.

SLIDE FLOCCULATION TESTS IN OFFICE PRACTICE

TO THE EDITOR:—Please publish a list of slide flocculation tests for syphilis and list their relative accuracy for office practice.

Paul J. Herley, M.D., Coatesville, Pa.

ANSWER.—There are no dependable slide flocculation tests for syphilis available for office practice. All tests for syphilis, including slide tests, are unique in the fact that the performance of each of the multiplicity of steps requires expert hands and an error in any one step is sufficient to lead to incorrect results. The dependability of syphilis tests is proportional to the expertness in serologic techniques of the technical worker who performs them.

TREATMENT OF EXPOSED ACHILLES TENDON

TO THE EDITOR:—Following an injury to the lower end of the lateral aspect of the right leg, an ulcer developed that laid bare about 2 in. of the fibula and about $3\frac{1}{2}$ in. of the Achilles tendon. Surrounding the exposed bone and tendon are healthy granulations that at both ends and on one side show no tendency to cover over the Achilles tendon. What treatment is advised to cover the exposed bone and tendon? What are definite signs of tendon death? Should this Achilles tendon be cut away at this time, seven weeks after injury? The peroneal tendons have already been sacrificed. What type of skin graft is best utilized to cover the defect? M.D., New York.

ANSWER.—An attempt should be made first to make sure the wound is thoroughly clean of any necrotic tissue. This can best be done by use of enzymes, such as streptodornase and streptokinase (Varidase), or cleaning the wound with hot, moist, normal saline packs. As to the death of a tendon, this is clinically difficult to determine. Some tendons, while appearing "dead," do have recuperative powers if given proper protection. The tendon should not be sacrificed at this time, but the defect should be covered with a thin, split-thickness skin graft. This will probably grow to the tendon and, in some cases, will even grow to the exposed bone. If the wound can thus be made into a closed wound, a secondary procedure can be done in shifting a skin flap, together with some fat with the flap, over the tendon. The fibula may later be resected; a 2 in. (5 cm.) resection of the fibula is of no consequence as far as function is concerned.

ADDITIONAL VARICOSITIES FOLLOWING TRAUMA

TO THE EDITOR:—A woman 50 years of age was in an automobile accident this summer. It resulted in pain and swelling of her right ankle and left knee and pain in the coccyx area without roentgenographic evidence of fracture at any of these points. Mild edema of the ankle and knee was present for several weeks. She has moderately severe varicose veins that she maintains are worse since the accident than they were before. Is it possible for trauma to an extremity to cause an aggravation of a previously existing varicose vein? G. L. Wiltse, M.D., Wahpeton, N. D.

ANSWER.—In order to prove a connection between the automobile accident and the presence of ankle edema with increase in the size or number of varicosities, the following points must be considered: 1. There was no ankle edema or less ankle edema before the injury than after it. 2. There was a type of collateral venous circulation characteristic of deep venous occlusion that now has definitely enlarged. 3. At present, there is evidence of deep venous insufficiency with superficial collateral network of veins. The occurrence of injury to a collateral venous bed, with increase of edema and appearance of additional varicosities, must be admitted since traumatic thrombosis is more apt to occur in a previously damaged venous network.

NEW METHOD OF CANNING CORN

TO THE EDITOR:—A large canning company announced that it was going to use a new method of canning corn that involved pressure cooking for only 7 instead of 30 minutes. Is a period of only seven minutes sufficient to kill botulinus spores? M.D., New York.

ANSWER.—The new method of canning corn to which the inquirer refers makes use of rotary-type equipment for holding the cans as they are being processed. By rotating the cans during the processing, a more rapid heat penetration is possible so that the holding time can be reduced. The usual processing for canned corn is 244 F for 30 minutes. With the rotary-type equipment, the processing is carried out at 270 F for seven minutes. It has been established by numerous studies that this high-temperature-short-time processing produces a better product and is at the same time adequate to insure the destruction of *Clostridium botulinum*.

EPIGASTRIC PAIN FOLLOWING INJECTION OF VITAMIN B COMPLEX

TO THE EDITOR:—While giving a malnourished patient a vitamin B preparation intravenously, he complained of severe, cramping epigastric pain of 2 minutes' duration. He gave a history of peptic ulcer a few years ago. I have had at least two patients with active ulcer complain of identical pain under the same circumstances. Is it usual for these patients to have irritation or spasm of the ulcer area from some component of the B complex? If so, could this reaction be of any value in following the progress of the peptic ulcer patient? M.D., Kentucky.

ANSWER.—There is no scientific evidence that suggests that the intravenous administration of any component of the vitamin B complex produces spasm of the stomach or duodenum in the region of an active peptic ulcer. The intravenous administration of a wide variety of chemical substances occasionally produces abdominal pain, with hypermotility or spasm of the colon and other parts of the gastrointestinal tract. In the present case, it would be necessary to demonstrate that the cramping epigastric pain following the intravenous administration of vitamin B is associated with spasm of the pyloric portion of the stomach and not of the colon. It is not likely that the reaction could be of value in following the progress of the peptic ulcer patient.

SODIUM FLUORIDE TABLETS AND DENTAL DECAY

TO THE EDITOR:—What is the present opinion of the value of sodium fluoride tablets for the prophylaxis of dental caries? K. W. Covey, M.D., Mahanomen, Minn.

ANSWER.—Theoretically dental benefits may be obtained from individual dietary supplements of soluble fluorides. There is, however, no adequate published study to verify this assumption, which is based largely on the observed results of water fluoridation. The obvious difficulties of individual administration relate to the following factors: 1. An optimum amount of fluoride must be administered daily throughout at least the first eight years of life to attain the dental benefits. There is also some evidence that continued use of fluoride beyond this period may be desirable. 2. The fluoride supplements must be adapted to the individual water supply or used only in areas where the drinking water is essentially free of fluoride. 3. Because of the potential hazards involved in the improper use of fluorides, such supplements should be limited to prescription in those cases that will be adequately supervised. The fluoridation of public drinking water is obviously the method of choice, but fluoride supplementation may prove useful in areas where a fluoridated municipal water supply is not available.

CARBON MONOXIDE POISONING

TO THE EDITOR:—I would like information on retrobulbar neuritis caused by carbon monoxide and optic atrophy caused by carbon monoxide.

Robert G. Laird, M.D., Grand Rapids, Mich.

ANSWER.—In the course of severe carbon monoxide poisoning as reflected by deep unconsciousness, almost any portion of the body may undergo damage. If persistent, such occurrences are to be regarded as sequelae and not as chronic poisoning. In all instances the damage is to be attributed to anoxia at the time of the acute episode. Brain tissue is particularly vulnerable. Fairly often involvement of the eyes will lead variously to transitory visual impairment or to total blindness or instead to ocular paralysis. Nearly always the lesions are located in the nuclei of the different ocular nerves rather than in any distal apparatus. On occasion the same condition has been described as optic atrophy or as retrobulbar neuritis without sharp discrimination. All this has been described by Drinker in "Carbon Monoxide Asphyxia" (London, Oxford University Press, 1938). That monograph contains bibliographic items referable to eye injury. Victims of carbon monoxide poisoning are prone to neuroses, and hysterical blindness or near blindness is well known.

ELIMINATION OF ALCOHOL FROM THE BODY

TO THE EDITOR:—Through what channel is alcohol excreted from the system of an inebriated person? How long does it take to excrete the alcohol from such a person? If a person's blood alcohol concentration was 0.15% four hours after his last drink, how much would it have been at the time of his last drink?

R. M. Sandeen, M.D., Buffalo, Minn.

ANSWER.—More than 90% of the alcohol is oxidized by the liver. The remainder is eliminated unchanged in the breath, urine, and perspiration. The rate of loss is remarkably uniform, a 150 lb. (68 kg.) person losing from 6 to 10 cc. of absolute alcohol per hour. The "catch" in the last question is that the last drink may also have been the first. Under such conditions there would have been no alcohol in the blood at the time of drinking, since it takes time for the alcohol to be absorbed into the blood. This phase of absorption, characterized by a rising blood alcohol, may last as long as two hours when a large amount of alcohol has been taken at one time. Then the oxidation factor supersedes and the blood alcohol level falls at a uniform rate of about 0.015% per hour. It is then simple to determine that the level four hours before a 0.15% reading could have been between 0 and 0.21%, depending on the phase of absorption or oxidation.

FAT IN THE DIET

TO THE EDITOR:—Is fat essential for the diet of a normal adult? If so, how much? What are the consequences of following an extremely low fat diet for many years?

M.D., Kentucky.

ANSWER.—It is probable that some fat in the diet is essential for the normal adult for the following reasons: (1) to supply certain essential unsaturated fatty acids; (2) to supply adequate calories to the total food intake; and (3) to supply satiety value to the total diet. However, it takes a relatively small amount of fat (about 25 gm. a day) to satisfy these requirements. Typical American diets are high in fat, containing from 125 to 175 gm. of fat per day. A "low fat" hospital diet will contain about 50 gm. of fat per day. There would be no adverse effects of following such a diet for many years.

EPINEPHRINE AND CARDIOVASCULAR DISEASE

TO THE EDITOR:—The answer about epinephrine and cardiovascular disease in the Dec. 19, 1953 JOURNAL, page 1496, requires modification. Epinephrine (Adrenalin) not aminophylline is the drug of first choice, but one must understand how to use it in relieving the asthmatic attack when associated with hypertension or cardiac disease. Too often the initial dose of epinephrine is too large, which accounts for the tachycardia. A dose of 4 minims should be injected subcutaneously. If within 20 to 30 minutes insufficient relief from the asthmatic attack is obtained, an additional 2 to 4 minims are administered until relief occurs, the total amount used being the optimum dose for any further attacks. Epinephrine is preeminent in the relief of the bronchial asthmatic attack with or without hypertension or cardiac disease, when used as advised. Aminophylline is the drug of choice only when the patient is epinephrine-fast or is sensitive to epinephrine. It is also a fine adjunct to epinephrine.

David L. Engelsher, M.D.

178 E. Mt. Eden Ave., New York 57.

AMOUNT OF ALCOHOL THAT CAN BE TOLERATED

TO THE EDITOR:—The reply in the Dec. 12, 1953, JOURNAL page 1414, on the amount of alcohol that can be tolerated I believe is rather on the conservative side. While in military service in the Philippines I observed a supply officer who consumed, by actual count, more than 40 cans of beer daily for several weeks—he bought it by the carton—during about 16 to 18 waking hours. During this time he was able to perform the duties required of him, and, while most of the beer was consumed after duty hours, I don't recall that he was ever out of contact with his surroundings.

Lester Lando, M.D., Monsey, N. Y.

OTOSCLEROSIS

TO THE EDITOR:—In THE JOURNAL Jan. 2, page 101, in *Queries and Minor Notes*, it was disappointing to see the brief handling of the subject on deafness under the heading "Otosclerosis." There was no accurate and detailed history given, no results of physical examination including nose, nasopharynx, and throat, and no functional examination of the hearing with tuning forks and audiometry. Conductive or nerve type hearing loss was not diagnosed; this should be done first.

Second, the commonest cause of bilateral progressive hearing loss with marked tinnitus is perceptive-type deafness and not otosclerosis. If it is otosclerosis, it is not true that any known therapy is useless. Many of these persons may have a satisfactory level of hearing restored by the fenestration operation. This operation, long past its experimental stage, is being done in numerous cities throughout the country. THE JOURNAL should print a correct answer so that some deaf persons will not be told that "nothing can be done except to get a hearing aid, learn lip reading," or worse to be relieved of tonsils and teeth.

L. Reed Cranmer, M.D.

Professional Bldg.

1838 Parkwood Ave.

Toledo 2, Ohio

TO THE EDITOR:—THE JOURNAL, Jan. 2, contains a rather inaccurate reply in *Queries and Minor Notes* purporting to answer a question on otosclerosis. The fenestration operation is no longer experimental and should have been recommended to this inquiring physician for his patient with otosclerosis. In fact, all otolaryngologists would be deeply affronted by this slight to the achievements of their specialty in this disease.

E. M. Herzon, M.D.

164 Division St.

Elgin, Ill.

TO THE EDITOR:—I would like to comment on the answer to the query on otosclerosis in THE JOURNAL, Jan. 2, 1954, page 101. The answer advises a young woman, aged 36, to wear a hearing aid. The fenestration operation, which has been so successfully developed in this country by Dr. Julius Lempert, should have been suggested. I have seen excellent results in patients on whom he operated more than 10 years ago, and four months ago he operated on a woman 60 years of age. In addition to progressive deafness she had other classic signs such as tinnitus and noises. She now has serviceable hearing, and the tinnitus and noises are gone for the first time in 30 years. This woman had tried a hearing aid. After wearing it a few weeks she became highly nervous. Her comment was: "I'd rather remain deaf than to have to wear it the rest of my life."

Joseph W. Miller, M.D.

1953 S.W. 16th Ave.

Miami 45, Fla.

The first of these letters received was submitted to the consultant who answered the original inquiry. His comment follows.

TO THE EDITOR:—In reference to the letter of Jan. 11 on otosclerosis, it may be said that a nerve type of deafness may be progressive in elderly persons (presbycusis); however, in a woman of 36, a nerve type of deafness is more likely to be stationary. With a presumed history of normal hearing, the deafness would be acquired in most instances from some injury or infection involving the eighth nerve. In this event the hearing loss would be stationary as a rule and would frequently be unilateral rather than bilateral. Otosclerosis is much commoner in my opinion, in women aged 36 than a bilateral progressive nerve type of deafness. Marked tinnitus is associated with otosclerosis rather than with a nerve deafness as a rule. The fenestration operation is most useful when indicated and is established as a sound surgical procedure. However it is not classed as therapy, as it does not affect in any way the progress of otosclerosis.

OPPORTUNITY FOR RESEARCH IN GENERAL PRACTICE

William B. Bean, M.D., Iowa City

The subject of this paper suggests that for a moment we have pause from the busy furor of our daily lives, back off a little, and think on where we are and whither we are going. Since this meeting is aimed consciously at the man in general practice, let us for a moment consider the horse-and-buggy doctor of 1953. His horses are not those literal beasts of burden and transport of his grandfather's time but rather engines of 100 horsepower, and the buggy, like as not, is a Cadillac. In his black bag are not just some tongue blades, a stethoscope, and a few specific and nonspecific remedies used with infinite effect but literally dozens of highly potent drugs—antibiotics, hormones, sedatives, vitamins—which he sometimes dispenses with bewildering liberality and abandon. Whereas his grandfather was the friend, adviser, and general sage of the families in his care, today the physician may be almost a stranger to the patient whose only contact with him is in the office or hospital. Certainly, having many more patients, he has less time to know each one well. A radical reversal in the public's attitude toward the physician has occurred so subtly that only when we hear otherwise sensible persons talk about socialized medicine as a panacea do we suddenly realize the long passages of time, space, and thought that physicians have crossed to get to their present pinnacle and present plight. For the commodity of health, the layman now feels, is a fifth freedom to which all are entitled as a birthright. How is the physician today prepared to serve those whose demands are exigent of all the miracles of the more flashy and superficial optimism of those popular elements of the lay press whose life blood is sensation and whose death sentence is the unadorned fact? In parallel with the growth of the great scientific aspects of medicine has been a decline of the medical arts that used to form the whole corpus of practice and that our grandfathers used with such happy effect. It is as though the mind and the attention of today's medical student and doctor could not absorb equally medical science and medical arts, the "Siamese twins" whose separation has always brought disaster when one or the other had to be sacrificed or left a runt. But the free practice of medicine must always be a practical art plus an applied science if it is to fulfill its best purpose. This brings us face to face with my theme, the

opportunity for research in general practice. A quotation from Sir James Mackenzie sets the stage: "Consider for a moment who is the individual in medicine who has the opportunity of seeing all parts of medical science in its true perspective. It is the general practitioner. He sees the conditions that predispose to disease; he sees its inception and the course it pursues, passing from the signs for medical treatment to the time when it calls for surgical interference. He sees the after-effects of the operation after the surgeon has claimed it as a success. If he is stimulated to inquire into the symptoms of disease, he is brought in contact with every special department, and has the opportunity for estimating them at their true value."

CHANGES IN LEADERSHIP

Two forces, I believe, have been responsible for the fact that leadership in clinical medicine, clinical research, or simply understanding the natural history of disease as it expresses itself in sick persons has passed from the hands of the yeomanry of medicine, the practicing doctors, into the ivory tower of our medical colleges, hospitals, and research institutes. First I put an uneasiness born of the belief that research is necessarily a matter of abstruse formulas, complex apparatus, and high voltage, which the novice had better leave alone. Thus the battle may be lost because the practicing physician enters the plea of *nolo contendere*, to use the lawyers' term. Far too many simply give up without a try. The other powerful influence, and it affects academic medicine, too, is nothing less than the deadening of natural curiosity, the suppression of wonder, and the security-minded acceptance of authority that characterize the attitudes of too many physicians who have come out of their medical school training with the rigid stamp of the stereotype ineradicably impressed upon them. The substance of my comments will be some review of the past and suggestions for the present.

HISTORIC ROLE OF THE GENERAL PRACTITIONER

The most striking phenomenon of our contemporary age of science is this languishing of those aspects of health and disease called natural history. They first came

into flower with the Renaissance. With the arousal from the long swoon of the human intellect known as the Dark Ages, the sterile authority of the ancients was exposed to the clear light of nature under the close and critical scrutiny of the inquiring mind. Jean Fernel, whose medical career epitomized the Renaissance, was a pioneer in advancing the medicine of his day by two bold steps. He escaped from the shackles of astrology, then recently given some dignity by the resurgence of mathematics but not yet become astronomy. He showed the false prognosis of horoscopes by following up predictions with facts. Next he eliminated magic from medicine, permitting observation to take its natural place. Thus he paved the way for Sydenham, to whom we owe the birth of modern clinical medicine, for Sydenham let the evolution of disease and epidemics write its own natural history. So, for a while, advances in medicine came mostly from the general physician who observed the whole life span of his patients, often literally from childbirth to death. He observed life, and what he saw was not to be found in the nosologies, systems, encyclopedias, or textbooks of the day.

By a curious distortion of ideas, research today has come to be thought of as an affair exclusively of the laboratory. The more complex the apparatus and equipment, the higher credit is given to the scientist. The doctor in practice is shy before such fame. The history of medical research in this country has many interesting facets. Up to relatively late in the 19th century, research as such hardly existed, although even then there were striking examples of physicians in general practice making elegant investigations. Beaumont's basic work in physiology clarified many abstruse problems of digestion. He took advantage of a rare opportunity that occurred in general practice. Drake's geomedical studies provided another example of the remarkable achievements in clinical observation, for Drake undertook nothing less than to describe and define the connection between geography and disease in the great interior valley of North America. Oliver Wendell Holmes, on the basis of his shrewd observations and deductions, was able to throw a clear gleam of light on the clinical havoc of puerperal sepsis long before the experimental science of bacteriology gave a detailed explanation for his observations.

One striking American characteristic has been the desire for immediate utility in the medical sciences. For this reason technology has ruled supreme. Pure science in this country only recently has come to stand on its own feet. The 19th century was fairly sterile in American contributions to basic science, but one can hardly blame the physicians of that era for contributing so little. They were products of the time in which they lived. In a capitalistic society their livelihood depended upon competitive solo practice; success in practice was the main requisite to high academic positions on medical faculties. The unfortunate thing about this was that the busy practitioner took little time for investigations. Comte has observed that such a situation was as bad for medical science as it would have been in astronomy had this field of endeavor been left up to the observations

of sea captains. Here the mariners provided the corrective of stubborn facts to keep theory compatible with practice.

ATTITUDES TOWARD PATIENTS AND DISEASE

Before this theme carries me away, I propose to digress for a moment on the nature of causes and the meaning of diseases. It might serve some modestly helpful purpose to consider some historic attitudes of physicians toward patients and diseases. In a broad and oversimplified way man has been thought of as an animal, a machine, or as a person with a soul. Disease has been a visitation of evil spirits, an error or flaw in an engine, or a complex biological reaction in time between a person and his environment, internal and external. This last considers etiology of disease in terms of person, mechanism, and surroundings seen as the momentarily stopped frame in a moving picture of infinitely various complexity. Now it is at once apparent that several viewers will see the same scene differently and the scene out of context with what has gone before may make little sense or may give false notions. We are confused or frustrated by coming into a movie at some unknown middle part. Disease as a biological reaction ceases to be an abstraction and becomes a concrete expression of forces, a person, and reactions. No one of the elements is absolutely comprehensible for us in terms of our best logic or symbols, so we judge the correctness of our impressions in terms of predictive value. Does our crude map tell us how to get there? Considering the great laxity of the human intellect when confronted with the need for reasoning and rationality and the fact that the data of science and observation are not the natural food of the mind, some of our maps are surprisingly accurate.

My particular plea is that the general practitioner as the family physician has a supreme opportunity and duty to observe his patients in this light and add to the corpus of knowledge, supplementing the microcosmic research of the laboratory and complementing the broad macrocosmic concepts of the philosopher of public health, in short, a normocosmic view of man.

CURRENT OPPORTUNITIES FOR RESEARCH

You may say uneasily that the laboratory researchers will come around to solving our problems for us, and to a degree this is true. But one of the subtle changes that has occurred whenever clinical research has achieved individuality as "clinical science" is that it has worked on its own problems with its own techniques. A salient feature of a specialized point of view is the natural preoccupation with its own problems. I need cite but one example. James Lind discovered all the essential features of scurvy—the circumstances of its occurrence, prevention, and cure—but it was 160 years before physiology and biochemistry came round to identifying and making vitamin C; and much of this delay was not because of want of skill but of lack of interest. The researches of our present-day leaders so often follow the template of the technique or the apparatus that much of what passes for investigation is the mechanical echo of a method. We find journals full of reports about electrolytes, iso-

topes, electrical potentials, intravascular pressures, and body compartments. Each modest pile of facts has some intrinsic worth. The trouble is that the machines of research often grind on from a long-forgotten *vis a tergo*. Thus the results may become the routine accumulations of pedestrianism not illuminated by ideas. Indeed, when some new idea does come along, the mad scramble to get into print produces a woeful rip tide of minor variations in the same eddies over the same shoals and reefs.

But, although it is heresy to say so, this is not my notion of real research or investigation. What are some of the important practical questions that, like so many wallflowers, are patiently waiting for our attention? What are the real causes for patients coming to us in trouble? Perhaps the simplicity of the complaints is unfashionable, but we owe them at least the courtesy of attentive thought. In the practice of medicine and, parenthetically, internal medicine is but a high-sounding name for the substance of general practice, many patients complain of troubles that have not yet had much attention from the laboratory. What light does science throw on that much-complained-of malaise or, more simply, the feeling of illness? What does it mean, how is it produced, what makes it fade into a neutral feeling and then vanish before the resurgence of the positive feeling of brisk and buoyant health? The answers await the natural historian of disease who attends sharply, observes faithfully, and thinks on the facts of observation in unrelenting meditation. It takes no atom smasher, no high-pressure mathematics, no ultracentrifuge to come to grips with the problem, but it does take time and it does take thought.

Pain, though it has recently received intense study, still contains in its universal variables much for the earnest thought of physicians in practice. Anorexia, nausea and vomiting, hunger, appetite, and satiety: these may be complaints volunteered insistently or unrecognized drives that lead the patient to peril or disaster. How little we know of their comings and goings! The steps from obesity to anorexia nervosa are few, but they are largely unmeasured. Fatness has, with reason, become a major preoccupation of our people, but the contradictory fads used to combat it bespeak our confusion or indifference. Surely those in touch with patients in many aspects of their lives are in a better position to investigate these problems in terms of significance and, perhaps indeed, of mechanism than are the laboratory people. Tiredness that comes without benefit of effort and fatigue that comes without work are pervasive symptoms that need the most careful probing and study. We need details of long and patient scrutiny to avoid the devil of seeing organic disease everywhere and the deep blue sea of ascribing every such complaint to emotional strain and stress. The physician who knows and has long known his patients, their families, fears, fights, failures, and festivals can illuminate such problems with insights hardly possible when the patient is abstracted from all his native surrounding and put in the context of the improbable or unreal world of a hospital bed or a department of clinical science. But work and care and time and thought are needed. There is no king's highway, no royal road.

NEED FOR DEFINITION AND CLARIFICATION

How much more we should know of sleep and rest and of insomnia, which some use as opportunity for reflection and others as excuse for impossibly exaggerated fishermen's tales of never sleeping. Even with all the studies by physiologists, psychologists, psychiatrists, and even psychoanalysts, the significant facts are meager and their interpretations myriad. But the place to get more facts is in the busy life of medical practice, by observations on patient, on family, and on self that may bring light to this dark and nocturnal study. And let us not leave constipation off our list. What is it? What are its significance and its mechanisms? What is the essence of its malfunction? Is there any good reason to subscribe to the fetid symbolism of the less self-critical devotees of the psychoanalytic school whose weird conceits and scatologic mythology bid fair to make them the scavengers and sewer men of the human spirit? Or should we instead rank costiveness as the number one enemy of the people and battle it by flooding this laxative-loving nation with still more cathartics? Even in this lowly problem the opportunities for research are handsome. The price is the same: observation, concentration, and meditation.

I have no doubt that the thoughtful man in practice could do something to clarify our tangled notions of what a vast deal of unrelated troubles hide behind that contradiction in terms, "intestinal flu," which may mean cancer, colitis, colic, or cramp. Another catch-all for the diagnostically destitute is "virus pneumonia"—the masquerade of abscess, tuberculosis, tumor, bronchitis, or bronchiectasis—treated too often with some handy antibiotic chosen by the eenie-meenie-minie-moe of the latest or most artfully lavish of that eager band of peripatetic scholars, the detail men. But when we "make the diagnosis," we have real patients suffering with real trouble and what we need is more painstaking study, care, and caution.

LACK OF BROAD PERSPECTIVES IN PATIENT CARE

Every thoughtful physician feels humility before the five modern plagues that have baffled all our wise men and defied the great committees of modern research that have launched project after project against one or another aspect of cancer, arteriosclerosis, hypertension, rheumatism, and the common cold. In the skeptical minds of a few of us, the feeling is gaining weight that research by caucus and committee will not yield the necessary clues. Broad, glowing light is not likely to come from the peep-show specialists who see the patient through the gun-barrel vision of their particular scope. Some of us feel that the answers in research, if they come at all, will come from ideas supplied by thoughtful physicians who employ their time in concentrated observation of the sick, which provides the driving force of imagination and sometimes, all unknown, permits a flash of insight. At a time when industry has found that pride in craft and contribution toward accomplishment is a stronger morale builder than wages or hours, we

should see to it that the lesson is not lost on those who by design or by fate practice medicine in swarms. There is real danger that our patient may disappear as an entity, John Smith, and become in fact that dry abstraction, the Common Man, whose conception is presided over by a conceptician, his birth attended by an obstetrician, his early days spent in the hands of a pediatrician, his burst into adult life in the hands of an adolescentist, and who during life is buffeted about among all the "-icians" and "-ists." At length he begins to become unstrung under the careful guidance of a climacterician. Finally the shriveling atrophy of old age is lubricated by the attention of a geriatrician until, bedeviled, bewildered, bemused, he falls exhausted off the end of the conveyor belt into the hands of the mortician. And all along the vast lock-step procession, teams and relays of specialists take turns at their posts on the day shift, the swing shift, and the graveyard shift, each to adjust one bolt, solder one wire, turn one screw, or take away bits of the wreckage; and the Common Man as he bounces along uneasily on his medical pilgrimage over the conveyor-belt road has no guide or companion unless he finds a personal physician.

INSIGHT THROUGH OBSERVATION

Whether from taste, talent, or training, my own investigations have all been done with the smallest amount of equipment and machines and have had their origin in questions I asked myself or those asked of me, for which I could get no answer from teacher or text. Some of the problems I list: the relation of syncope to sudden death¹; organic disease as a cause of secondary malnutrition²; the growth of fingernails³; vascular spiders, palmar erythema, cherry angioma, venous stars, and caviar lesions⁴; and precordial noises and rupture of the aortic valve.⁵ None of the investigations required expensive apparatus. They were done at the bedside or in the office. All could have been done in general practice. In these fields of observation and research I made no revolutionary discovery, but there has been some tidying up, some clarification and synthesis aiming at general principles. This merely underscores the fact that we need many workers to get any of those rare flashes of insight that light up our dark probings and advance medicine.

These miscellaneous comments around the theme of research in general practice defy concise summary. They are predicated on the profound conviction that nature, instead of being explored exhaustively, holds back great expanses of unknown terrain. Even in what seems well-

mapped land, many things need to be cleared up, and sometimes our most cherished maps are obsolete. We need new ones. In this great garden of nature we need many workers, for the human intellect, though a sharp and wonderful tool, has never been an easy one to use. Systems and doctrine hold back progress, partly because they can never hope to encompass the whole of nature. Much current medical training by its rigid conformity to artificial systems helps overload the mind with detail. Our childhood wonder is finally strangled by what passes for education, and we live as strangers in a strange world. Not the least of our professional blunders is the failure to cultivate in all practicing physicians the capacity to observe, to meditate, and to synthesize. I get very tired of being told that a research program will start when the machine arrives and then of watching the perplexity as to what to study with it when it comes. In no sense are these remarks antiscientific, and I bow my head in awe and humility before the magnificent structure of modern science. None of us would give up the great advances attained by concentration in narrow fields.

THE FIFTH ESTATE

Fortunately the several aspects of medicine are not mutually exclusive. But the practical arts of medicine are too much jostled by experimental science from above and applied science from below. For its right development this trinity must have reasonable equality of the three constituent parts. Experimental science alone may be the sharp edge of an overhoned blade that curls back on itself unless supported by the practical arts. Applied science rapidly becomes dogma unless corrected constantly by the stubborn facts of clinical trial and observation. And the practical arts of medicine degenerate into quackery unless supported by experimental and applied science. To illustrate, each new scientific instrument introduced into medicine has left its wake bestrewn with faulty diagnoses before clinical experience plus scientific research put it into proper perspective. The stethoscope and electrocardiograph are ready examples.

To the lords spiritual, the lords temporal, and the commons, Edmund Burke added the Fourth Estate, the lay press: I conclude by urging that we all undertake to join in and share the rigors and torment but also the glories of what Arthur D. Little called the "Fifth Estate . . . composed of those having the simplicity to wonder, the ability to question, the power to generalize, the capacity to apply. It is, in short, the company of thinkers, workers, expounders, and practitioners upon which the world is absolutely dependent for the preservation and advancement of that organized knowledge which we call Science. . . . The world needs most a new tolerance, a new understanding, an appreciation of the knowledge now at hand. For these it can look nowhere with such confidence as to the members of the Fifth Estate. Let us, therefore, recognize the obligation we are under. Ours is the duty and the privilege of bringing home to every man the wonders, the significance, and the underlying harmony of the world in which we live."

SURGERY OF THE ELDERLY

John D. Stewart, M.D.
and
Guy S. Alfano, M.D., Buffalo

The relative and absolute increase in the number of elderly persons in this country is a statistical fact that the medical profession must face. The elderly, as a group, are less able to pay for private medical care, and therefore they comprise an enlarging proportion of the clinical material available for ward teaching. The situation is not entirely without advantages on a surgical service. The lowered physiological reserve of the aged, the high incidence of concomitant disease, and the too commonly advanced nature of their surgical lesions constitute a challenge and demand the best the surgeon and his team can give. Much can be learned from close attention to the surgical care of the aged, and principles of broad significance must be reckoned with. Such points form the basis for an expanding literature dealing with the surgery of the elderly.¹

During a recent one year period at the Meyer Memorial Hospital there were 290 major operations on a consecutive series of 204 general surgical patients over the age of 70 (table 1). The average age of the 204 patients was 76.8 years, and the oldest patient was 94. The operations included laparotomy, thoracic surgical procedures, hip nailing, amputations, herniorrhaphy, thyroidectomy, sympathectomy, radical neck dissection, radical mastectomy, and other major procedures. Diagnostic endoscopy was not included in the tabulation. The over-all mortality rate was 13%, and the rate of postoperative complications was 35%.

Study of these cases brought out the point that these elderly patients were commonly being referred for surgical care for only the most compelling reasons. Advanced disease was the rule rather than the exception. Gastrointestinal cancer with complications, calculous biliary obstruction, incarcerated or strangulated hernia, intestinal obstruction, and gangrene of the lower extremities comprised a large proportion of the lesions. In the 95 laparotomies, cancer of the gastrointestinal tract was present 42 times, and in eight patients the lesions were far advanced and inoperable.

Considering the age of these patients and the severity of their disease, one must conclude that the surgical operations were well tolerated. It has been noted by others that laparotomy is a severe test for the elderly.² In the present series of 95 laparotomies there were 18 deaths, or 19%, and convalescence was unmarred by complications in 63%. Of the 95 laparotomies 42 were done for cancer, with 14 deaths, giving a mortality rate of 33%, though in 8 of these patients the growth could not be removed. In the 53 laparotomies done for lesions other than cancer there were four deaths (7.5%). Similarly, there were 22 operations on the biliary tract, with three deaths, but two of the deaths were in patients with unremovable cancer of the gallbladder and bile ducts. After the 18 operations for calculous disease of the gallbladder and bile ducts, there was only one death.

The 41 operations for hip nailing were followed by eight deaths. Four of these occurred more than one month after operation, death being due to pneumonia and inanition. The herniorrhaphies are also of interest in this connection. In the 32 operations, with no deaths, 2 involved laparotomy for repair of sliding hernia; and in four instances emergency repair was required. In two patients gangrenous bowel was excised.

MAJOR ABDOMINAL SURGERY

In a separate study designed to evaluate the risk of major abdominal surgery in patients over the age of 70 who have lesions other than cancer, further evidence of the surgical hardihood of the elderly was obtained. As shown in table 2, during a six year period there were 43 gastric resections for complicated peptic ulcer in patients over 70 years of age. The average age was 74.4 years; the oldest patient was 88. There were four deaths, three of which occurred after gastric resection for the arrest of acute massive hemorrhage in patients whose total red cell mass had been reduced to 60% or less in hemorrhage of life-endangering severity. In two of the four deaths the cause was myocardial infarction, which occurred on 2 and 29 days, respectively, after operation. One patient died of severe encephalomalacia, probably initiated by the hemorrhagic shock for which he was operated on. The fourth patient died of purulent bronchitis eight days after gastric resection.

An emergency gastric resection for acute massive hemorrhage from duodenal ulcer was performed on an 88-year-old man. He received 3 liters of blood during the operation, and his recovery was rapid and complete. His systolic and diastolic blood pressure dropped from 130/65 to 75/30 in the first hour of ether anesthesia, with subsequent stabilization at slightly above the original level. The free transfusion of blood as well as the cautious use of vasoconstricting drugs was in order to control such hypotension.

POSTOPERATIVE COMPLICATIONS

In analyzing the postoperative complications in the series of 290 operations on 204 patients over the age of 70, as shown in table 3, the commonest complications observed were those affecting the respiratory system, the

surgical wound, and the cardiovascular system. After 190 operations, no complications were noted. The high incidence of respiratory complications points up the need for using antibiotic drugs properly, maintenance of good oxygenation during anesthesia, avoidance of postoperative immobility, use of narcotics only sparingly, free use of pharyngeal and tracheal suction to remove postoperative secretions from the airway, and minimal use of nasogastric indwelling tubes. Fluid therapy, and particu-

larly the administration of sodium chloride solutions, must be carefully controlled, and this frequently requires laboratory measurements.

There was a fairly high incidence of wound complications, such as infection, dehiscence, and hematoma, but it must be remembered that a high proportion of these patients had cancer, impaired peripheral blood flow, and malnutrition. In many instances laparotomy incisions in the elderly heal rapidly and firmly, and one gets the impression that wound complications are the result of factors other than age itself. In this connection, the importance of restoring and maintaining normal hemoglobin values in the elderly should be stressed. In the absence of acute blood loss, the transfusions should be given slowly, but the amounts of blood should be adequate. When it is feasible, hemoglobin and plasma protein values should be brought to normal before operation, and in this connection blood volume determinations can provide precise guides.³ Specific nutritional defects are common in the elderly and must be considered in surgical care.⁴ In bedside examination there is often evidence of lack of such factors as the water-soluble vitamins.

The occurrence of cerebrovascular accidents after operation in the elderly is of special interest, and there were five such instances in this series (table 3). It is of the utmost importance, as pointed out above, to avoid fluctuations in blood pressure and blood flow in these patients. Atheromatous plaques in the arteries of the brain, heart, or kidneys may be the site of formation of fatal thrombi during periods of stagnant flow. Hazardous intravascular clotting may also occur in the arteries and veins of the lower extremities or of the gastrointestinal tract. The anesthetist must keep this consideration foremost, and adequate oxygenation, together with minimal essential muscular relaxation, must be achieved without gross disturbance in hemodynamics. It is not always possible to prevent shifts in blood pressure during major abdominal surgery. The patient indicated in figure 1 was a 94-year-old woman with gastric cancer extending into the gastrocolic ligament. The resection was done entirely with the patient under local anesthesia, and the blood pressure and pulse reactions during radical gastric resection are shown in the chart. She was given 750 cc. of blood during the procedure. The hypotension occurring at the end of the first hour of anesthesia may have been due to splanchnic block or mesenteric traction. Fortunately, no untoward results followed, and the patient appeared to be in good health six months later. In studying the anesthesia reactions of this group of patients during the 290 operations, 40 patients were noted to have hypotension (systolic blood pressure below 90 mm. Hg) at one time or another. In 3 of these 40 patients cerebrovascular complications developed after operation. On the other hand, after the 250 operations performed without hypotension during anesthesia, cerebrovascular accidents occurred only twice. A pancreatoduodenectomy for carcinoma of the head of the pancreas was performed on a 72-year-old man. He lost about 200 cc. of blood and was given one liter by transfusion. His pulse and blood pressure remained fairly even throughout the long and complicated operation.

Fig. 1.—Blood pressure and pulse reactions during gastric resection for carcinoma in a 94-year-old woman.

If the operation and the immediate postoperative course can be conducted without anoxia and with little disturbance in blood flow, severe coronary artery disease or previous myocardial decompensation do not contraindicate necessary surgery. Figure 2 shows the blood pressure and pulse reactions of an illustrative case during operation. A 71-year-old physician had suffered two attacks of myocardial infarction, four and two years previously. He was left with angina and had experienced

4. Elman, R.: Surgical Care: A Practical Physiologic Guide, New York, Appleton-Century-Crofts, Inc., 1951.

mild decompensation. A large sliding inguinal hernia could not be supported by a truss and made the patient's life miserable. Repair was successfully carried out, and no blood was given the patient, because his nutrition was good and blood loss at operation was minimal. He left the hospital eight days later and returned to his practice. At follow-up examination six months later there was no recurrence of the hernia.

MAJOR THORACIC SURGERY

The question is often raised as to the tolerance of the elderly patient for major thoracic surgery. There is mounting experience suggesting that such procedures

Fig. 2.—Blood pressure and pulse reactions during repair of sliding hernia in 71-year-old man.

are borne as well as extensive abdominal surgery. A 75-year-old man came into the hospital because of cough, weakness, loss of 40 lb. (18.1 kg.) in weight, and chest pain of eight months' duration. A right pneumonectomy was performed for squamous cell bronchogenic carcinoma, involving the regional lymph nodes. One liter of blood was given during operation. When the patient was seen five and one-half years later, he had had no recurrence of carcinoma and was in reasonably good health.

A 71-year-old woman complaining of attacks of weakness and convulsions over a period of six months was admitted to the hospital. Mental deterioration had been noted. A diagnostic study led to the diagnosis of hyperinsulinism and probable islet-cell tumor of the pancreas. By means of the combined thoracoabdominal approach an islet-cell adenoma of the body of the pancreas was found, and resection of the pancreas and splenectomy were performed. One liter of blood was given during the operation. Two years later the patient's health had remained good.

COMMENT

An analysis of the chief complications in the fatal cases of the present series is shown in table 4. It was concluded that in 21 of the 39 deaths the fatal outcome probably had little relation to the surgical operation, though this is, of course, speculative. Seventeen of the 39 patients who died had advanced cancer, and if these deaths were excluded the mortality rate was approximately 8%. Respiratory and cardiovascular complications were most commonly noted in the fatal cases.

It has been pointed out that the daily routine of the elderly patient should be upset as little as possible in relation to surgical treatment, and the patient should be returned to his normal environment as soon as practicable.⁵

In considering the problems of preoperative and postoperative care of the elderly, one is impressed with the point that they differ only in degree as compared with surgical care of younger patients. The margin of safety is less, and sharper attention to details is requisite. Expert nursing care is a potent factor in the recovery of the elderly patient, particularly if he be apathetic, querulous, disoriented, or negligent. Several students of the subject have recently pointed out the need for precise and accurate study of the physiological changes of senescence.⁶ It can be hoped that further scientific progress in gerontology will provide the clinician with better guides in evaluating the physical fitness of the elderly patient and his capacity to handle unusual stress. The statistical approach to the problem is hardly satisfying when the clinician has to make a decision in the case at hand.

At the risk of oversimplifying the subject, the following rules are suggested as desirable procedure in the surgical care of the elderly: (1) maintenance of normal values for hemoglobin and plasma protein, (2) free use of antibiotics, (3) proper vitamin therapy, and (4) postoperative pharyngeal and tracheal suction to keep the airway clear. The following factors are considered to be undesirable: (1) immobilization and inactivity, (2) stage operations that prolong morbidity, (3) anoxia and deep anesthesia, (4) fluctuations in blood pressure and blood flow, (5) overhydration, and (6) extremes of temperature or position. In addition, nasogastric suction by indwelling tube should be used minimally and narcotics should be given only sparingly.

* Consecutive series of 204 general surgical patients over age 70. There were 39 deaths and 17 autopsies.

SUMMARY AND CONCLUSIONS

An analysis is presented of 290 operations on 204 consecutive patients over the age of 70 admitted to a general surgical service and subjected to major surgical procedures. No postoperative complications were noted after

5. Morton, J. J.: Surgical Care of Patients in the Extremes of Life, *Am. J. Surg.* 30: 92, 1935.
6. Lansing, A. I.: Some Physiological Aspects of Ageing, *Physiol. Rev.* 31: 274, 1951. Carlson, A. J.: Physiologic Changes of Normal Aging, in *Geriatric Medicine: The Care of the Aging and the Aged*, Steigltz, E.-J., editor, ed. 2, Philadelphia, W. B. Saunders Company, 1949, p. 47.

190 operations, or 65%. The commonest complications that occurred in the remaining 35% involved the respiratory system, the cardiovascular system, and the surgical wound. There were 39 deaths, or 13%, 17 of which occurred in patients with terminal cancer. If the latter are excluded, the mortality rate was 8%. Twelve of the deaths occurred in patients who had senile psychoses in addition to their surgical lesions. Advanced disease was the rule rather than the exception in causing these patients to be referred for surgical care.

It may be concluded that (1) major surgical operations can be carried out in the elderly with reasonably low risks; (2) the lowered physiological reserve of the elderly requires close attention to details of surgical care and technique; (3) serious concomitant disease does not necessarily contraindicate needed surgery; and (4) adequate surgical care should be made available to the elderly not merely to save life but also to relieve discomfort and disability.

ANTIBIOTICS IN MANAGEMENT OF AMEBIASIS

Gordon McHardy, M.D.

and

William W. Frye, M.D., Ph.D., New Orleans

The comprehensive management of amebiasis includes supportive therapy, prophylactic measures, and the proper administration of applicable amebicides. This treatise does not include methodical discussion of the factors involved in general patient care. Severity of the diarrheal stage or of the complications may necessitate bed confinement and hospitalization. Dietotherapy during the acute stages may be restricted to frequent small feedings of bland liquids. The therapeutic response and less austere aspects of the disease permit progression through bland diets to a relatively normal low residue nutritious regimen. Chronic mild and asymptomatic phases dictate only nutritional requirements. Abstinence from use of certain substances has been advocated, including alcohol,¹ defatted hog gastric tissue (ventriculin),² and certain food substances.³

The clinician's contribution to the prophylaxis of amebiasis is restricted to the direction and treatment of persons with parasites. An aggressive attitude inestimably aids the public health officer, whose problem is prevention of contamination of food and water supply. The meticulous study of the direct contacts of each patient is the physician's responsibility. Eradication of *Endameba histolytica* from all persons with the parasites, both those with and without symptoms, is imperative as a public health measure.

The initial amebicide, ipecac, has been discarded. Emetine,⁴ the first efficient and widely used amebicide that was initially considered "specific," has, despite its proved *in vitro* efficiency, fallen into relative disuse. Therapeutic limitation⁵ and toxicity⁶ dictated its early decline. The only existent indications for its administra-

tion are as a supplement in the control of unusually severe amebic dysentery and for extracolonic amebiasis. Various emetine combinations with bismuth and iodine have not been endorsed in this country.

The iodine compounds chiniofon⁷ (yatren, anayodin), Vioform (5-chloro-iodo-8-hydroxyquinoline),⁸ and Diodoquin (5,7-diiodo-8-hydroxyquinoline)⁹ are still in common use. Of these, Diodoquin is least toxic and is accredited with good results.

Various arsenicals have proved efficiency. Carbarsone,¹⁰ acetarsone (Stovarsol),¹⁰ Treparsol (a formyl derivative of 3-amino-4-hydroxyphenylarsonic acid),¹¹ thiocarbarsone (4-carbamido-phenyl bis[carboxymethylthio] arsenite),¹² and arsthinol (Balarsen)¹³ have been advocated. Arsenical toxicity, a potentiality of each, reserves them in most instances for cases which other therapy has been unsuccessful. The combination of arsenic and bismuth as bismuth glycolylarsanilate (Milibis)¹⁴ is endorsed as an efficient relatively nontoxic amebicide. Carbarsone has also been widely used.

Extraintestinal amebiasis, considered metastatic from colonic involvement, necessitates dual therapy. Most amebicides are limited in their efficacy to colonic involvement. Specificity, however, characterizes emetine and chloroquine, which, while effective for such involvement, are restricted in efficacy for colonic eradication. Emetine hydrochloride, which was the only effective drug for extraintestinal amebiasis before chloroquine diphosphate was developed, is still endorsed when parenteral administration is imperative. Efficiency and relative freedom from toxicity has rendered chloroquine the drug of choice. For complete therapy, however, both emetine and chloroquine must be supplemented by an agent efficient for colonic eradication of *E. histolytica* and prevention of liver involvement. The combination (Milibis-Aralen) of chloroquine (Aralen) with bismuth glycolylarsanilate is the result of this conclusion. Aspiration of abscesses is often imperative, even with an efficient therapeutic program.

Antibiotic literature shows a trend toward establishment of protozoacidal efficiency. Nutritional and invasive aid accredited to intestinal bacterial flora rationalizes applicability. Therapeutic evaluation of the antibiotics against

Read before the Section on Gastroenterology and Proctology at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

The following drugs were supplied by the makers for use in this study: oxytetracycline (Terramycin) and carbomycin (Magnamycin) by Chas. Pfizer and Company, Brooklyn; chlortetracycline (Aureomycin) by Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y.; and fumagillin (Fumadil) by Abbott Laboratories, North Chicago, Ill.

E. histolytica had its inception with Hargreave's¹⁵ contention of adjunctive penicillin action. Thereafter, publications varying from individual case reports to extensive survey and military sponsorship of various commissions have indicated the intensity of a search for a more satisfactory amebicide.

Extremes in therapeutic achievement, on analysis, suggest variance in susceptibility of parasitic strains, diversity in case severity, inconsistency and inadequacy in follow-up, and lack of uniformity in the mode of antibiotic administration. A sincere attempt to summarize this information was obvious in the conference "Use of Antibiotics in Tropical Diseases," conducted by the New York Academy of Sciences.¹⁰ Therein, however, appeared a conglomeration of individual treatises, little correlation, no acknowledgment of conflict, and a lack of conclusiveness derived from combined opinion.

Several excellent analyses of antibiotic efficacy confined to individual group experiences have been published.¹⁷ No attempt has been made to establish potency, interpret results, or indicate final resolution of the conflicts in therapeutic opinion. Further, two newer antibiotics, fumagillin (Fumadil)¹⁸ and carbomycin (Maganamycin)¹⁹ have entered the field of amebicides for evaluation.

It seems conceded that penicillin and streptomycin act on the bacteria.²⁰ Penicillin and streptomycin alone and in combination have been used to control bacterial growth in *E. histolytica* cultures and to assist in establishing strains of amebas in culture with single strains of bacteria. High concentrations of these two antibiotics have little or no effect on *E. histolytica* in culture.²¹ Streptomycin and penicillin have no value as amebicides.²² Synergism to increase efficiency is suggested in limited study.²³ The therapeutic potentiality of prodigiosin is nullified by its toxicity.²⁴

Chloramphenicol, early recognized as a potentiator of blood dyscrasias²⁵ and an inefficient amebicide,²⁶ should not be considered an acceptable antiamebic substance. The results with bacitracin²⁷ have not been uniformly favorable. From our observations neither neomycin nor erythromycin can be considered more than adjunctive at the present time. Carbomycin, one of the newer antibiotics of promise, is primarily effective against only certain bacteria. It simulates the wide spectrum antibiotics only in antirickettsial and protozoacidal influence. Seneca and Ides²⁸ demonstrated inhibition of *E. histolytica* in cultures of carbomycin, indicating its amebicidal potentiality. Amebicidal efficiency of carbomycin is suggested in early observations but the inadequacy of our follow-up and inept administration of resistant enteric-coated tablets invalidating a group of our studies modifies any conclusion we might have at this time.

Statistics garnered from the literature combined with our own experience permits this therapeutic tabulation for the antibiotics in amebiasis. We are continuing our studies on carbomycin in the treatment of amebiasis. Table 1 summarizes the reports on antibiotic treatment of amebiasis. In this compilation oxytetracycline (Terramycin) holds an enviable position. Fumagillin in a less extensive (numerically) survey is 86% efficient. Chlortetracycline (Aureomycin) is third in efficacy.

Obviously, the other agents are too ineffective to be considered for other than complementary use with an effective direct-acting amebicide. While the incidence of failure indicated here suggests the therapeutic limitation of the antibiotics, we believe there is no panacean amebicide. Further, in this series estimates are based on efficiency of a single agent rather than of combined treatment as in many reports.

Oxytetracycline, chlortetracycline and fumagillin have been used most widely with the most favorable acclaim. These three therefore should be considered individually.

Chlortetracycline.—Chlortetracycline was extracted from a species of *Actinomyces* in soil by Duggar in 1947.²⁰ It is an effective, readily absorbed, wide-spectrum antibiotic.³⁰ Said to be toxicologically benign in therapeutic doses, it frequently precipitates side-effects of consequence that are predominantly gastrointestinal.³¹ Chemical, fungal and hypovitaminotic glossitis, stomatitis, pharyngitis, esophagitis, gastritis, colitis, and proctitis occur.

Because of its wide-spectrum antibacterial action, it is more readily assumed to be an indirect acting amebicide. Hewitt, Spingarn, and associates³² have speculated

TABLE 1.—Summary of Reports on Antibiotic Treatment of Amebiasis

Antibiotic	No. of Patients	No. of Recurrences	Failure Incidence

that it has direct action. Phillips³³ confirmed this in his culture of *E. histolytica* with *Trypanosoma cruzi* in the absence of bacteria of any kind.

Experimentally parasitized rats responded to chlortetracycline in Jones' study.³⁴ Other observations were contradictory.³⁵ Watts and Vandegrift cultured strains resistant to chlortetracycline.³⁶ Shaffer and Washington³⁷ did not observe resistance to chlortetracycline, oxytetracycline, or emetine hydrochloride in two strains of *E. histolytica* after 38 serial transfers. Clinical successes were first reported by McVay and his associates.³⁸ Their conclusions were enthusiastically endorsed on incomplete and brief follow-ups by Hughes,³⁹ Gutch,⁴⁰ and associates,^{26a} Most, Conn,⁴¹ Siguier,⁴² Armstrong,^{17c} and others. Because of reports of recurrences,⁴³ treatment with chlortetracycline began to fall into disrepute,⁴⁴ and its use is now completely discredited.⁴⁵

Our experience with chlortetracycline has not been favorable. The report of a 32.2% failure rate by one of us (W. W. F.)^{17a} and a 40% recurrence rate by the other (G. McH.)^{45c} is illustrative. The results in a series of 18 cases at the local Veterans Administration Hospital are postulated favorable with only two recurrences, but the follow-up was inadequate. Beyond this, in a 12 month period we have had 38 patients with amebiasis report for therapy who still had cysts of *E. histolytica* despite recent treatment with the assumed effective dose of chlortetracycline (500 mg. every six hours for a total of 20 gm.).

Comment.—Despite some persistent optimism,⁴⁶ it must be conceded that chlortetracycline has definite limitations as an amebacidal substance. Above and beyond this, the frequency and severity of gastrointestinal side-effects on such a therapeutic regimen often contra-indicate use of this agent.

Oxytetracycline.—Oxytetracycline was developed in 1950.⁴⁷ Its toxicity was recorded as minimal.⁴⁸ Its side-effects in some aspects simulate those of chlortetracycline. With wide-spectrum antibacterial influence, it is thought to be a potential indirect amebacidal substance. Direct action has been difficult to establish.

Tobie and his associates⁴⁹ in their comparative study endorsed oxytetracycline for its “apparent effectiveness of 100%.” Favorable but more reserved reports emanated from many sources.⁵⁰ The situation as summarized by Most and Van Assendelft⁵¹ indicates oxytetracycline is surviving a two year trial, still commended as an effective amebicide. This report is the first with an adequate long term follow-up. Lack of response in hepatic involvement is recorded and amebic abscess of the liver has developed during oxytetracycline therapy.^{45b}

The experience of one of us (W. W. F.)^{17a,d} concurs in an extensive study, which unfortunately did not permit a prolonged follow-up. In a study limited to 18

TABLE 2.—Evaluation of Fumagillin as an Amebicide in Fifty-Nine Cases with a Twelve Month Follow-Up

	Total No.	No. "Cured"	No. with Recurrences	Acute	Passing of Cysts
Acute amebic dysentery.....	10	8	2	1	1
Chronic amebic dysentery.....	18	18	0	0	0
Asymptomatic passing of cysts	31	27	4	0	4

patients treated with 500 mg. every six hours for a total of 20 gm. in which a 12 month follow-up was achieved, we have had only one recurrence (or reinfection), which was encountered at the six month examination. However, in 11 of these patients, there was an antibiotic-induced diarrhea that persisted an average of five weeks into the post-therapeutic period. Severe stomatitis developed in six persons. Of 17 patients treated with oxytetracycline in the local Veterans Administration Hospital, only one has had a recurrence, but the follow-up was inadequate. If intensive and prolonged therapy is not necessary, some side-effects may be avoidable. During a 12 month period we have encountered 11 patients with persistent amebic parasitization after treatment with a dose schedule of 250 mg. every six hours for a total of 5 gm. prior to seeing us. An additional four patients had been adequately treated by competent observers with recurrence.

Comment.—The generally favorable reports indicate oxytetracycline is an efficient amebicide after adequate trial. Significant side-effects and a definite recurrence rate mitigate against over-enthusiastic acceptance without reservation. No claim for management of extraintestinal amebiasis is endorsed. An over-all 92% “cure” rate is better than that obtained with any of the antibiotics or other amebicides.

Fumagillin.—Isolation of fumagillin was reported by Hanson and Eble in 1949.¹⁸ Initially considered an anti-phage, relatively devoid of antibacterial and antifungal activity, it appeared to be a direct acting amebicide on in vitro studies of McCowen, Callender, and Lawlis.⁵² Evaluation on *T. cruzi* cultures by Hrenoff and Nakamura confirmed amebacidal potency.⁵³

In animals amebacidal efficiency without alteration of intestinal bacterial flora⁵⁴ or appreciable toxicity has been acclaimed.⁵⁵ Its innocuousness was confirmed in man.⁵⁶ Killough indicated vertigo and anorexia as side-effects at 50 mg. daily dosage; dermatitis, nausea, and emesis were precipitated by a daily dose of 200 mg.⁵⁷ Our report indicated intolerance to a dose beyond 60 mg. daily.^{45c} The most frequent side-effects encountered have been nausea, cramping lower abdominal discomfort, distension, and mild diarrhea. These have not approached contraindicative significance, subsidence occurring with or shortly after therapy. Occasionally post-therapeutic vague malaise and superficial desquamation of the hands and feet occur.

Laboratory surveys during and after therapy have shown no significant departure from normal.^{45c} A single patient had post-therapeutic leukopenia with marrow depression but had an uneventful recovery; exacting investigation to estimate a coincidental or precipitated relationship is proposed.

Comparative therapeutic evaluation between fumagillin and two other agents, oxytetracycline and thiocarbarzone, was conducted by Anderson.^{55a} Initial dosage inadequacy is indicated in his report, as suggested and confirmed by the author himself, and is probably substantiated by more recent surveys, all of which enthusiastically report preliminary successes.⁵⁸

During a 17 month evaluation period we have administered fumagillin to 228 ambulatory patients. A preliminary report indicated follow-up difficulty.^{45c} We have discarded all cases in which we could not make personal observations and all instances of incomplete, interrupted, or adjunctive therapy. We did not include patients in this study who had extraintestinal amebiasis.

All patients were treated for 10 consecutive days. The minimum dose schedule was 10 mg. of fumagillin three times a day. Most patients received 20 mg. of fumagillin three times daily. Table 2 shows results obtained with fumagillin therapy.

Fifty-nine patients from our preliminary report^{45c} (of 64 cases) were available 12 months following therapy. These comprised initially 10 instances of acute amebic ulcerative colitis, 18 patients with chronic amebic ulceration, and 31 asymptomatic persons parasitized with *E. histolytica*. In this group there were six recurrences (or reinfections) after therapy. Three were mentioned in the initial report, two of these occurring within the third month and the third at the sixth month examination. The remaining three recurrences (or reinfections) were encountered in the ninth month post-therapeutic check. Re-treatment with fumagillin has been successful in two for six months, but a third has had further recurrence. The remaining three patients on re-treatment were free of parasites in an average follow-up period of 10 weeks.

Comment.—Fumagillin has survived enthusiasm in an adequate evaluation period and is confirmed as an efficient innocuous amebacidal agent if there is adherence to recommended dose levels. A recurrence incidence recorded with fumagillin, as with other therapeutic agents, indicates its limitation and confirms an opinion expressed in 1945, "No one drug is always a successful and complete amebicide." It has not been evaluated in extra-intestinal amebiasis and is probably not therapeutically applicable to such complications.

IN VITRO AMEBACIDAL EVALUATION OF ANTIBIOTICS

Efforts to establish a reliable screening mode whereby efficacy could be established by in vitro survey have been exhaustively studied. Cultural techniques from their

cetin) have a direct effect on several strains of *E. histolytica* grown in a "preconditioned" medium⁶⁴ in the absence of actively multiplying bacteria. In conjunction with us, Shaffer has studied the action of additional antibiotics against several strains of *E. histolytica* in vitro.

The medium employed in this report for maintaining strains of *E. histolytica* used for testing is essentially a "preconditioned" thioglycollate medium to which penicillin G in 0.85% sodium chloride solution and horse serum was added. The fluid thioglycollate medium (no. 136, Baltimore Biological Laboratory) is preconditioned by an anaerobic gram-negative *Streptobacillus* that is cultured in the medium for 24 hours at 37.5 C.⁶⁵ The cultures are then centrifuged, and the supernatant fluid used

initial successes in 1928⁵⁹ indicated bacterial growth requirements for *E. histolytica*.⁶⁰ Nonbacterial cultivation with *T. cruzi* was accomplished by Phillips⁶¹ and has offered a completely nonbacterial medium for testing. Balamuth,⁶² who sponsored egg yolk infusion cultures, conservatively evaluated the various cultural modes and their applicability to in vitro estimates with a plea for greater uniformity in standardization of cultural methods. Although the in vivo conclusions determine the true efficacy of an agent, the screening of preparations for clinical trial may be simplified by an efficient in vitro testing mode. Action in vitro may not be a true evaluation of the amebacidal activity in vivo. Inconclusiveness as to whether direct or indirect amebacidal action occurs with broad-spectrum antibiotics obviously projects itself.

Shaffer and his associates⁶³ have obtained evidence that chlortetracycline and chloramphenicol (Chloromy-

as a base for the *E. histolytica* cultures. The addition of penicillin G prevents active multiplication of the streptobacilli remaining in the supernatant fluid after the majority of the bacterial cells are centrifuged out.

The strains of *E. histolytica* used in this study were inoculated into the "preconditioned" medium and incubated for 48 hours at 37.5 C. The cultures were examined after this period of incubation, and those showing 4+ growth of *E. histolytica* (25 to 50 per low power field) were used for the tests.

Each antibiotic tested was weighed on an analytical balance and dissolved in 0.85% sodium chloride solution to proper concentration, and serial twofold dilutions were made, also in saline. One milliliter of these dilutions was then added to appropriate tubes of amebas. The concentrations were calculated so that the first tube had a final concentration of about 10 mg. per milliliter

of the antibiotic, the second tube 5 mg., and so on for nine tubes. The last tube always received 1 ml. of saline and was used as a control. This range gives an end point on each drug tested. The final volume of the tubes is 4.8 mg. per milliliter; the 1.0 ml. of drug solution added must contain 48 mg. of drug.

Table 3 shows the effect of oxytetracycline, chlortetracycline, chloramphenicol, carbomycin, and fumagillin on several strains of *E. histolytica* maintained in the Shaffer-Frye medium. Since there are few if any actively multiplying bacteria in these cultures of *E. histolytica*, these results indicate a direct action of antibiotics on the amebas in culture.

It is interesting to note that with strain K-14 fumagillin did not cause the disappearance of the amebas in high concentrations but was effective against two other strains in much lower concentrations. Carbomycin was effective against duplicate cultures of K-14. The *E. histolytica* strain K-14 was isolated by one of us (W. W. F.) from a patient with acute amebic dysentery in Korea during the summer of 1951. This strain has been in culture for a much shorter period of time than the other strains used in this study. It must also be noted that the effect of fumagillin at the end of 24 hours and 48 hours differs somewhat from the other antibiotics tested.

These in vitro studies with other strains of *E. histolytica* are being continued by Shaffer in an attempt to determine whether other strains of *E. histolytica* may be resistant to one or more of the antibiotics now used in the treatment of amebiasis. If additional positive evidence of difference in the reactions of various strains to the action of antibiotics does occur in vitro, it may help to explain why certain patients are not cleared of their intestinal infection with *E. histolytica* when treated with one of the antibiotics.

IN VIVO AMEBACIDAL EVALUATION OF ANTIBIOTICS

Working in cooperation with us, Dr. Alfred Longacre attempted to determine recoverable antibiotic in stools following oral administration of oxytetracycline and carbomycin. A review of the literature pertaining to the titration of antibiotic levels in stool specimens, either in vitro or in patients receiving antibiotic therapy, did not reveal any accurate technique for estimation of the amount of antibiotic in the stool. The reports referring to the amounts of antibiotic in stool specimens are restricted to an indication of its presence, or, in some instances, a rough estimate as to the possible percentage of antibiotic in the stool is made. In trying to determine the action of antibiotics and possibly the effective dose level of antibiotics in amebiasis therapy, we thought detailed knowledge of the concentration of the antibiotic in the stool would be of importance. Because of this interest in stool concentration of antibiotics administered orally, a technique, which will be reported in detail later, has been developed. This technique gives consistent results in that 64% of the antibiotic added to a normal stool may be recovered. A correction factor is made on the basis of recoverable antibiotic when the titrations are run in conjunction with a saline control coincidental to the titration.

By this technique for determining the amount of recoverable antibiotic in the stool, the level of antibiotic after oral administration has been studied. In repeated tests in volunteers it has been found that 500 mg. of oxytetracycline given every six hours will result in a concentration in the stool of from 300 to 600 mcg. per gram of stool in from 15 to 20 hours. In a volunteer receiving the antibiotic over a long period of time, there was no significant elevation of the concentration in the stool, which suggests that there is little or no accumulation factor in repeated dosages. Oxytetracycline and carbomycin have been studied, but only preliminary data are available at the present time. These studies will be continued and a complete report presented later. These preliminary results obtained after oral administration of two antibiotics to normal human volunteers must not be interpreted in a clinical sense, and a clinical evaluation of the dose level concentration of the various antibiotics in the stool will have to await a clinical trial controlled by indicated titrations.

Spontaneous recovery, not commonly recognized, has been shown to occur in a recent study of a large series of cases of acute amebic dysentery,^{17a} and this fact must be given consideration in the evaluation of any specific therapy. Certain enterococci by production of lactic acid have been shown to inhibit amebic growth⁶⁵; pigment produced by chromobacterium organisms is also toxic to protozoa.⁶⁶ Either mechanism must be considered in interpretation of in vitro studies.

COMMENT

There is need for a detailed study of the natural history of the *E. histolytica* to explain the many variants encountered. Beyond this our analysis justifies additional amelioration. In the chlortetracycline series, the average patient received 20 gm. over a 10 day period. There were many individual exceptions. Probably all instances of a dose schedule of less than 10 gm. in a 10 day period should be discarded. Were such restriction exacted, there would nevertheless be little difference in the over-all picture, so no departure is indicated.

In the oxytetracycline patients 20 gm. over a 10 day period was more rigidly adhered to. Abbreviated therapeutic periods have been emphasized as being effective, and departures from the schedule were unusual. The general uniformity of therapy therefore has resulted in a more exact evaluation for oxytetracycline.

With fumagillin caution characterized initial studies; a definitely inadequate program resulted in unfavorable early reports. We have sponsored administration of 600 mg. in 10 days. Individual intolerance has demanded some variability in dosage. The optimum program probably lies between 300 and 600 mg. during a 10 day period. Were cases in which this schedule was not met discarded, the general picture would be definitely more favorable for fumagillin. Because the reported cases are fewer than with the two other products, we refrained from any alteration of the statistics.

In follow-up observations a pronounced variability is obvious. With few exceptions, studies after chlortetracycline therapy did not extend beyond six weeks. Many studies were even limited to the treatment period alone, rendering a mean average follow-up of less than four

weeks. With oxytetracycline, the picture is slightly more complete. Most studies were carried beyond the six weeks. One large series assisted in bringing the average follow-up to a mean of eight weeks. The fumagillin situation is materially altered by our extended study. In study of fumagillin we achieved an average follow-up of more than eight months. Obviously both recurrence and reinfection will be increased by extended surveys. This factor depresses the results further with chlortetracycline, probably alters the favorable position of oxytetracycline, and sponsors the position of fumagillin. Under normal circumstances, follow-up study should be continued for three months after therapy.

SUMMARY AND CONCLUSIONS

A composite evaluation of the amebicidal efficacy of the antibiotics is attempted. The difficulty of *in vitro* estimates is reemphasized. The advantages of screening

new amebicides are depicted, with the prospectus for a more accurate mode of study. Despite the inaccuracies obvious in most clinical reports, they must be the basis for true therapeutic evaluation. A dosage schedule should be worked out on a more accurate basis for each antibiotic under trial as an amebicide. Of the broad-spectrum antibiotics, oxytetracycline (Terramycin) is the drug of choice in the management of intestinal amebiasis. Chlortetracycline (Aureomycin) is less efficient. Fumagillin (Fumadil), obviously a direct-acting antibiotic because of its restricted bacterial spectrum, is an efficient amebicidal substance. There is some evidence that combined therapy may be more efficient than any antibiotic alone because of the distinct difference in mode of action and the depicted therapeutic limitation. Hepatitis, hepatic abscess, and other extracolonic amebic involvements are not benefited by treatment with the antibiotics evaluated.

MODERN TREATMENT OF HIRSCHSPRUNG'S DISEASE

Orvar Swenson, M.D., Boston

Hirschsprung's disease (congenital megacolon) is a congenital malformation of the pelvic parasympathetic system consisting of absence of ganglion cells in Auerbach's plexus in a variable portion of the distal colon that is supplied by the pelvic nerve. The length of colon involved in this ganglionic deficit varies but always includes the internal sphincter, the rectum, and rectosigmoid.¹ The lesion may extend more proximally, but rarely beyond the sigmoid. In some instances longer portions of colon may be involved, but rarely the whole colon; and in these situations a congenital malformation exists in the vagal fibers that supply the colon to some point in the sigmoid, as well as the pelvic parasympathetic nerve that supplies the remainder of the colon.

The detection of the congenital lesion in the intestine wall can be made on histological sections stained with hematoxylin, eosin, or other routine tissue stain. That special stains are required to identify the ganglion cells of Auerbach's plexus is a common misconception. Cells are found in clusters between the circular and longitudinal muscular layers, and the average-sized histological section of intestine wall invariably contains some of these large ganglion cells. They are easily recognized because of their large size, finely granular cytoplasm, large nucleus, and prominent nucleolus. These cells can be identified accurately in frozen sections of colon wall, and this technique is used at operation to assure that all of the aganglionic intestine is resected.

The congenital absence of Auerbach's ganglion cells is probably related to the failure of normal peristalsis to traverse the affected intestine. The colon proximal to this segment has a normal distribution of ganglion cells, and peristalsis of normal amplitude and progression is present. This absence of peristalsis in the distal colon accounts for the intestinal stasis and the well-known symptoms of this disease.²

PROCEDURES IN DIAGNOSIS

Children with constipation can be divided into two groups. Those with chronic constipation due to bad habit or a psychogenic cause have an onset of constipation at 2 or 3 years of age. Patients with the rarer Hirschsprung's disease have a history of constipation dating from birth, and frequently symptoms are severe enough during the first few days of life to simulate ileal obstruction. Some consequently have been explored with that diagnosis.

Examination of the patient gives further information that aids in the differentiation of these two groups of patients. Children with chronic constipation on a habit basis rarely have abdominal distension; however, patients with Hirschsprung's disease have varying degrees of distension, and it is rarely completely absent. Rectal examination offers another clue to the correct diagnosis. Children with habit constipation have impactions in the rectum; whereas patients with Hirschsprung's disease usually have impactions in the sigmoid above the congenital lesion, and the rectum is empty.

While these symptoms and signs are helpful in determining whether the patient has true Hirschsprung's disease, surgery should not be done until the diagnosis has been confirmed with a barium enema. This examination is difficult to perform, and painstaking attention must be given to several details. A small amount of barium should be injected and observed fluoroscopically with the patient in an oblique or lateral position. The flow of

2. Swenson, O.; Rheinlander, H. F., and Diamond, I.: Hirschsprung's Disease: New Concept of Etiology; Operative Results in 34 Patients, *New England J. Med.* 241:551-556 (Oct. 13) 1949.

barium is stopped as soon as the contrast media partially fills the dilated portion of the colon. Filling the sigmoid loop completely may obscure the outline of the rectosigmoid, which must be clearly visualized for the diagnosis.

Unless there is a dramatic narrowing over a distance of 8 to 10 cm. with marked dilatation of the colon above, the diagnosis of Hirschsprung's disease cannot be made (fig. 1). Observation of slight narrowing, 2 to 3 cm. in length, in some portion of the sigmoid, with dilatation of the colon above and below, is not sufficient for a diagnosis of Hirschsprung's disease. Another important roentgen sign is the inability of the patient with Hirschsprung's disease to empty the colon, and this loss of function should be recorded on a postevacuation

Fig. 1.—Roentgenogram demonstrating narrowing of the rectum and rectosigmoid with marked dilatation of the sigmoid. This is pathognomonic of Hirschsprung's disease.

roentgenogram. Dilatation of the colon of itself is of little diagnostic value, for this condition may be due to a number of causes, particularly chronic constipation.

RESECTION OF AGANGLIONIC INTESTINE

Resection of the aganglionic rectum and rectosigmoid and performance of a pull-through anastomosis is a difficult operation that must be performed with precision to assure good results. It should not be undertaken unless the surgeon is experienced in this field and completely understands this intricate procedure.³ In 122 patients it has been possible to resect all of the aganglionic intestine down to the internal sphincter and to re-establish continuity of the colon without disturbing anal

continence.⁴ Recently it has been suggested that only the portion of aganglionic intestine above the pelvic peritoneum should be removed. This was suggested by State on the supposition that impotence would be the inevitable result if the resection were performed down to the internal sphincter.⁵ In the series of 122 patients

Fig. 2.—A, photograph of a 10-year-old boy with advanced Hirschsprung's disease. B, same patient one year after resection. Abdominal contour has returned to normal.

there have been 4 adults whose ejaculation has not been disturbed by resection of the aganglionic intestine to the internal sphincter. In 43% of the patients the lesion extended only to, or just above, the pelvic peritoneal floor. If only a segment of colon above the pelvic floor were resected, this group could not be helped by such an operation, for little, if any, aganglionic bowel would be removed. The 55% with lesions extending above

Fig. 3.—A, preoperative roentgenogram of patient with Hirschsprung's disease. B, repeat barium enema on the same patient three months later. The colon can be emptied.

the pelvic floor would be helped by a resection but not completely relieved. Furthermore, leaving a 5 to 8 cm. length of aganglionic intestine in these patients would, over a period of time, cause recurrence, as has been reported by Hiatt.⁶ It is hard to justify a procedure that leaves a segment of aganglionic colon in place equal in

length to the defective segment in some patients who have fairly severe disease. If patients with Hirschsprung's disease are to be treated surgically they should have a complete procedure, which consists of removing all of the aganglionic colon.

RESULTS

There have been 5 postoperative deaths in 122 patients operated on; 4 were infants under 8 weeks old who were in extremely poor condition and one was a child 2½ years old. Two of them had preliminary colostomies, and in three the resections were primary. The causes of death in this group of patients were as follows: In one there was recurrence of the disease, because the resection had not extended far enough proximally; this infant did not do well after the first operation and died after a second resection. Another patient died because of intestinal obstruction with formation of fistulas between loops of small intestines. A third patient died with bilateral adrenal hemorrhage a week after operation. The fourth patient was an infant with a severe congenital heart lesion. The fifth patient, a child with megalobladder and megaloureters, as well as megacolon, tolerated the resection but died one week later following a severe generalized convulsion.

There have been some complications postoperatively. One severe stricture was due to a poor technical anastomosis. It occurred early in our experience and fortunately has not been encountered again. There has been one rectovaginal fistula resulting from a suture that was inadvertently placed through the posterior vaginal wall as the anastomosis was made. This patient had colostomy performed two months after the resection, and the fistula closed spontaneously. The colostomy was closed a year later, and the patient is doing well without any evidence of recurrence of the rectovaginal fistula. There have been minor urinary infections but no impairment of bladder function.

The patients tend to have diarrhea for a few weeks following operation. This gradually subsides, and the patients then have one to two bowel movements a day. They have normal urge to evacuate the colon and have adequate movements daily without help of diet, laxatives, or enemas. The abdominal distension disappears in the course of eight months to a year (fig. 2). The colon gradually returns to essentially normal size, and, most important, emptying of the colon occurs (fig. 3). Some of the patients have been followed for as long as six years.

CONTROL OF TRICHINOSIS BY GAMMA IRRADIATION OF PORK

Sylvester E. Gould, M.D., Eloise, Mich., Henry J. Gomberg, Ph.D.

and

Frank H. Bethell, M.D., Ann Arbor, Mich.

The effect of exposure of trichinous pork to gamma irradiation as a possible means of controlling the disease trichinosis in swine and man has occupied our attention during the past 18 months. By way of introduction, it might be well first to outline the cycle of trichinous infection. In man, trichinosis is contracted from ingestion of meat (nearly always pork) containing viable larvae of *Trichinella spiralis*. In hogs, the principal source of infection is trichinous pork eaten as scraps discarded from the kitchen. On ingestion of the infected meat, the muscle fibers and the cyst walls that enclose the parasites are digested, liberating the larvae. In the small intestine the larvae mature in three or four days to adult worms that then copulate. Toward the end of the first week, gravid females partially embedded in the mucosa of the intestine begin to give birth to young larvae of the second generation. It is believed that, during the next few weeks (in man 8 to 10 weeks), each female gives birth to about 1,500 larvae that enter the intestinal lymphatics and then the blood stream; from there they are carried into the general arterial circulation. The young larvae leave the capillaries and penetrate the skeletal muscle fibers, where they progressively enlarge, coil, and encyst during the ensuing four weeks. Except in the remote possibilities of the eating of human flesh by rats, especially where burial is above ground, or of cannibalism, the parasitic cycle in man ends with the completion of the stage of encystment, but the encysted parasites

generally remain alive in a latent state, without producing symptoms, for the rest of the life of the infected person. In hogs, however, the parasitic cycle is continued when uncooked, or insufficiently cooked, meat of a trichinous pig is eaten by another pig.

Symptoms of human trichinosis may be divided into two broad groups: (1) gastrointestinal symptoms that generally occur during the first or second week after infection and are the result of irritation of the intestinal tract by the ingested larvae and the adult worms that develop from them and (2) general symptoms that occur during the ensuing three to five weeks and result from dissemination of the second generation of larvae in the body of the host, particularly from their localization in the skeletal muscles and from complications of the disease.

About 1.5% of all hogs slaughtered in the United States are infected with larvae of *T. spiralis*. We believe that, as a result of eating trichinous pork, about 25% of all Americans during their lifetime will harbor the para-

From the Atomic Energy Commission Laboratory on Biological Effects of Irradiation, the Michigan Memorial-Phoenix Project, University of Michigan, Ann Arbor, Mich., and the departments of pathology, University of Michigan, Ann Arbor, Wayne County General Hospital, Eloise, Mich., and Wayne University College of Medicine, Detroit.

Read before the Section on Pathology and Physiology at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

This study was carried out under Contract No. AT (11-1)-75 for the United States Atomic Energy Commission at the University of Michigan and as part of Project No. 54 of the Michigan Memorial-Phoenix Project.

site in their muscles. The average mortality among persons with clinical trichinosis in the United States is 5 to 6%.

Of all pork produced, only the relatively small proportion that is processed by heating, freezing, or other method, according to governmental regulations (principally in packing plants that are under federal inspection), is free from the danger of trichinosis. Such products, offered for sale to be eaten without need for cooking them further, carry the implied warranty of their fitness for human consumption. Raw pork, however, even when bearing the stamp "U. S. inspected and passed," carries no such warranty. The consumer of pork, therefore, generally must be responsible for avoiding trichinosis by determining, if he can, whether all portions of the pork or pork product that he is about to eat are thoroughly cooked and show no trace of pink.

Fig. 1.—Section of trichinous ham in which have been placed a number of dosimeters consisting of capsules of ferrous sulfate solution to calibrate dose of gamma radiation at different points in the meat. The screen cage behind the meat rests on a platform over an opening that communicates with a pit in the ground in which the cobalt 60 source lies beneath 14 ft. (430 cm.) of water. The cobalt source is raised by remote control into the screen cage for the desired period of irradiation.

The following methods are designed to prevent trichinous infection: 1. Microscopic inspection of specimens of pork from the carcass of every hog slaughtered is practiced in Germany and some other countries of Europe and South America but is regarded as impractical in the United States. 2. Cooking of all garbage that is to be fed to hogs is in force in England, Canada, and a number of states in the United States and is of unquestioned value in control of trichinosis as well as of certain other diseases

of hogs, including vesicular exanthema, hog cholera, and hoof-and-mouth disease. The chief limitation of the method, however, lies in the difficulty of constant enforcement. 3. Low temperature treatment (5 F for 20 days for packages of pork not over 6 in. [15.2 cm.] in thickness) can be used; while a temperature as low as -34.6 F (-37 C) will kill trichina larvae within a few minutes,¹ the production of this low temperature in all portions of the meat is relatively time consuming and economically impractical at present. 4. Special methods of processing can be required by the federal government in U. S. inspected plants for pork and pork products that will be sold for consumption without further treatment. 5. Cooking should be thorough so that every portion of the pork is heated to a minimum temperature of 137 F.

In actual practice in the United States, the principal method for protection against trichinosis is adequate cooking of pork. This means that at the present time the responsibility of cooking pork adequately, and thus avoiding trichinosis, rests principally on the housewife or cook. The consumer generally does not examine the pork that he eats to determine if it has been cooked adequately. Even if he were to examine the meat, he would often be unable to decide if cooking was adequate. Furthermore, in many meat products, such as hamburgers, frankfurters, meat loaf, chop suey, and some sausages, the consumer generally does not know if pork has been added. In eating pork and meats containing pork, he, knowingly or unknowingly, often risks contracting trichinosis. An effective method of prevention or control of the disease in this country, therefore, is needed.

During the past year and a half we have been studying the effects of gamma radiation as a possible new method for the control of trichinosis by irradiation of raw pork. In a previous study on the effect of 200 kv. x-rays on trichina larvae, Gould, Van Dyke, and Gomberg² showed that a relatively large dose (750,000 r) is required to kill trichina larvae in vitro but that much smaller doses (3,500 to 5,000 r) are effective in preventing the reproduction of trichinae. Exposure of trichinous meat in thickness of less than 1.5 cm. to x-radiation in a dose of 15,000 r rendered the larvae in the meat noninfective to experimental rats.

Gomberg and Gould³ then studied the effect of cobalt 60 on trichina larvae and obtained similar results. A dose of 750,000 r was required to kill the larvae in vitro. When trichinous rat meat was irradiated, a dose of 15,000 r produced sexual sterilization of the larvae, and a dose of 18,000 r prevented 99% of the larvae from maturing to adult forms. Our present work concerns the effects of exposure of trichinous pork to gamma irradiation of Co⁶⁰ and of waste fission material contained in old nuclear fuel rods.

METHOD

Two pigs, a barrow and a gilt, each about 3 months old and weighing about 120 lb. (54 kg.), were each infected with about 60,000 isolated larvae of *T. spiralis* in their feed on Dec. 24, 1951. At the time of slaughter 16 and 17 months later, respectively, each of the hogs weighed about 450 lb. (204 kg.). The concentration of larvae per gram of muscle in the barrow was 267 in the tongue, 345 in the diaphragm, 73 in the ham muscles, and 44 in

the leg muscles; in the gilt, 590 larvae per gram of tongue were recovered and 152 per gram of shoulder muscle.

Large portions (except for one, each portion weighed about 50 lb. [23 kg.]) of the trichinous pork from these hogs were exposed to gamma irradiation from a 10,000 curie source of Co^{60} at the Fission Products Laboratory of the University of Michigan. This source is housed in a specially constructed room and is operated by remote control.⁴ When calculated from measurements made with r-meter chambers, the dose of irradiation delivered at 17 in. (43.2 cm.) from the source was 13,200 r, and at 8½ in. (21.6 cm.), 34,000 r. In general, the irradiated meat was excised in segments that measured about 4 by 4 in. (10 by 10 cm.) in surface area and 2 in. (5 cm.) in thickness. The dose delivered to each segment of meat varied approximately in inverse proportion to the square of the distance from the source; the dose also varied

pork, a large ham, was exposed for 5 hours and 20 minutes to a total calculated dose ranging from 3,000 to 9,400 r. A second portion of pork, a shoulder, was exposed for 20 hours, resulting in doses ranging from about 13,000 r to about 60,000 r. A detailed description of the technical aspects of the irradiation experiments will be published elsewhere. In all, 21 sections of meat, each selected for a given dose range, were tested for the effect of gamma radiation from the fuel rods.

In each experiment a number of segments of the irradiated meat were excised and digested for recovery of larvae. Four control white rats were each fed by stomach tube with 5,000 larvae isolated from nonirradiated pork, and usually four test rats were each fed with 5,000 larvae isolated from each segment of the irradiated meat. At six days, two control rats and half (usually two) of each group of test rats were sacrificed and the contents of their

* Portion of meat measuring 20 by 17 by 9 in. (50.8 by 43.2 by 22.9 cm.) and weighing 50 lb. (22.7 kg.) was exposed to 10,000 curies of Co^{60} for a half hour on each side, at distance of 12 to 13 in. (30 to 33 cm.) from source (center about 17 in. from source).

† Based on the calculation that the dose 10 in. (25.4 cm.) from the surface was equivalent to 50% of the dose at the surface.

‡ Each number represents the finding in a single rat.

because of absorption of radiation passing through the meat. Measurements were made by means of r-meter chambers, a Victoreen rate meter, and by capsules containing ferrous sulfate solution placed at designated points in the meat (fig. 1). Six tests with Co^{60} were done; 35 pieces of irradiated trichinous pork were tested.

In addition, two portions of trichinous pork, each weighing 50 lb. were irradiated with fission products contained in old fuel rods from reactors obtained from the Hanford, Wash., laboratory of the Atomic Energy Commission. These rods, containing uranium, are the basic operating elements of nuclear reactors. The irradiation was carried out under 20 ft. (610 cm.) of water in the storage canal of the Chemical Processing Plant of the National Reactor Test Station at Idaho Falls, Idaho. The effect of the radiation on the trichinae was correlated with the dose reaching a given area in the meat by measuring the radiation with chemical dosimeters distributed through the meat. One of the two portions of

small intestines examined for adult trichinae. From each rat sacrificed at this time, 50 or 100 female adult worms were examined for the presence of embryos in the uterus. At 30 days, the other two control rats and the other half of each group of test rats were sacrificed and their skeletal muscles digested and examined for the presence of young larvae. Microscopic sections also were taken from the tongue, diaphragm and muscle of an extremity for the presence of young larvae. In all, 56 pieces of meat were tested and 225 white rats were used in these experiments. The details of the technical methods of recovery of larvae and adult forms of trichinae are given elsewhere.⁵

RESULTS

Table 1 shows that, when portions of trichinous pork were exposed to doses of 9,500 to 10,350 r of Co^{60} , sexual sterility was produced in 74 to 98% of the gravid female

5. Gould and others.² Gould, S. E.: Trichinosis, Springfield, Ill., Charles C Thomas, Publisher, 1945.

adult trichinae recovered from the intestines of test rats after six days. When a dose of 11,830 r was given to the meat, sterility was found in 100% of the female adults. Figure 2 presents these findings graphically. Figure 3 is a

Fig. 2.—Sterilizing effect of cobalt 60 irradiation on trichina larvae in pork. After irradiation, 5,000 larvae from the meat were tube-fed to test rats. seen is a newborn young larva that has just been expelled from the vulval opening. Figure 4, taken at a higher magnification, shows an adult female trichina of the same age recovered from the small intestine of a test rat six days

after the latter was fed trichina larvae digested from trichinous meat exposed to 10,240 r of Co^{60} . The parasite is shorter than normal, its cuticular covering is thickened, and the cells are lacking in detail and apparently undergoing degeneration. No eggs or young embryos can be recognized in the uterus, the worm having been rendered sterile by radiation applied to it during its larval stage.

In table 2 the calculated lowest dose of Co^{60} applied was 12,000 r. In three of four test rats, no adult trichinae were recovered, but in a fourth rat 650 adults were found and all of 100 female adults examined were sterile. These findings agree with those shown in table 1, in which it is indicated that sterilization was produced by a calculated dose of 11,830 r. Table 2 also shows that among 16 rats fed larvae from meat exposed to 19,200 to 23,660 r of radiation, 7 of 8 had no adult trichinae in their intestinal tract after six days and one (exposed to 20,700 r) had

Fig. 4.—Sterile adult gravid female *Trichinella spiralis* ($\times 180$) showing stunting of growth and degenerative cellular changes after exposure to 10,240 r of cobalt 60.

three partially developed sterile female adults. Two factors lead to a nonuniform dose of radiation in the meat: (1) Absorption of radiation by the meat and (2) loss in strength of field of radiation as the distance from the source is increased. Owing to absorption alone, it was found that in a large portion of pork (20 in. [50.8 cm.] in thickness) the value of the surface radiation falls to half when the radiation reaches a depth of 10 in. from the surface, and with application of an equal amount of radiation to each surface, at the same distance, the dose at the center of a 20 in. mass of pork will be 80% of the dose at each surface. In practice, however, the variation resulting from distance will increase this differential in some manner, depending upon the shape of the source and the distance of the source from the meat.

COMMENT

Alicata and Burr^a exposed trichinous rat meat to 12,000 r of gamma radiation of Co⁶⁰ applied over a period of four days and found that sterility was produced in 60 to 100% of the adult female worms developing in the intestinal tract from larvae present in the irradiated meat. In our experiments with trichinous rat meat a single dose of 12,000 r gamma radiation of Co⁶⁰, applied over a period of about 10 minutes, produced sterility in from 80 to 100% of adult females and a dose of 15,000 r produced sterility in 100%. The results of irradiation of pork with Co⁶⁰ agree well with findings in our previous experiments on irradiation of trichinous rat meat with Co⁶⁰. In trichinous pork a dose of approximately 15,000 r was required to produce complete sterilization and a dose of approximately 18,000 r to prevent maturation of larvae to adult forms.

In the trichinous pork exposed to the fuel rods, conditions of operation could not be adequately controlled inasmuch as the meat had to be suspended over the irradi-

adult trichinae or prevent maturation of the larvae to adult forms will break the trichina cycle and thus prevent the development of the muscular phase of trichinosis in the potential host. It may not, however, prevent the development of gastrointestinal symptoms in the host, which occur in approximately one-half of clinical cases of human trichinosis as a result of irritation of the small intestine by the parasites which partially penetrate the mucosa.

In a small percentage of persons with gastrointestinal symptoms, diarrhea may be a serious event, particularly if it is severe, long maintained, or occurs in an aged or debilitated person. It is also possible for the number of living larvae ingested with the infected meat to be so large as to produce acute fatal enteritis. Preliminary experiments indicate that, when white rats are fed larvae exposed to only 10,000 r, in numbers equal to a fatal dose of nonirradiated larvae, the animals at most will suffer a temporary diarrhea, presumably as a result of irritation of the intestinal mucosa by the larvae. Irradia-

† Based on the calculation that the dose 10 in. (25.4 cm.) from the surface was equivalent to 50% of the dose at the surface.

‡ Each number represents the finding in a single rat.

ator with a 20 ft. rope and the radiation dose varied markedly with the position of the meat with respect to the radiator. Among other disturbing factors was shrinkage of the rope as it absorbed water. By use of dosimeters inserted in the meat, information obtained regarding the doses given was more accurate than would be possible merely from observation of the position of the meat with respect to the irradiator.

The radiation from the fission products appeared to produce the same results regarding sterilization of trichina larvae as were obtained from Co⁶⁰ radiation in doses about 10% higher. Since the spectrum of radiation from the fuel rods could not be obtained, however, the reason for this somewhat higher effectiveness could not be determined. The chief implications from these tests are that irradiation by fission products is as effective as Co⁶⁰ in breaking the trichina cycle and that further studies are necessary under conditions that are more adequately controlled.

In applying the findings to possible commercial irradiation of raw pork as a means of controlling trichinosis, it is obvious that a dose that will either produce sterility of the

tion thus appears to suppress the observed intestinal effects on feeding of intact larvae. The extent of this suppression, as a function of the dose of radiation, is now being studied. It would, therefore, be best if the dose of irradiation to trichinous pork be large enough to prevent maturation of the larvae to adult worms. From our findings a dose of 18,000 to 20,000 r would accomplish this. Practically, it would seem that a margin of safety of about 50% should be allowed, so that the dose of irradiation recommended for prevention of maturation of the larvae should be increased to 30,000 r. However, further experimental work is being conducted to determine the effect of feeding massive numbers of larvae from trichinous pork irradiated at this dose. By actual tests made in the Fission Products Laboratory of the University of Michigan, no flavor changes detectable by taste and no known deleterious effects were induced in pork exposed to approximately 40,000 r of irradiation with Co⁶⁰. There is, of course, no radiation stored in the meat as a result of

6. Alicata, J. E., and Burr, G. O.: Preliminary Observations on Biological Effects of Radiation on Life Cycle of Trichinella Spiralis, Science 109: 595-596, 1949.

gamma irradiation, and there is no known harmful effect that can be produced in a person from ingestion of such irradiated meat.

Since Co^{60} represents a form of nuclear radiation that is induced, it is quite expensive at present. Waste fission products of "atomic" radiation may be cheaper and theoretically could be used to yield the desired amount of radiation inexpensively and rapidly. Further investigations are being conducted along these lines.

SUMMARY AND CONCLUSIONS

The results of irradiation of trichinous pork with cobalt 60, and of a preliminary study of irradiation with waste fission material contained in old nuclear fuel rods, agree with our previous findings on effects of Co^{60} on trichinous rat meat. These results indicate that exposure of all raw pork to gamma radiation of waste fission products may be a practical means of controlling trichinosis in man and pig.

POLYPS OF RECTUM AND COLON

Neil W. Swinton, M.D., Boston

The intimate relationship between benign mucosal polyps and cancer of the colon and rectum (fig. 1) has been generally recognized, particularly by surgeons and pathologists who have had a special interest in this disease. Several general statements can be made that summarize this relationship. (1) Benign mucosal polyps of the rectum and colon occur in both sexes, slightly more commonly in males than in females, and at all ages. They occur with increasing frequency in the older age groups. (2) Polyps are frequently multiple and are found in our experience in approximately 25% of all surgical specimens removed for cancer of these organs. (3) There is a definite similarity between the age incidence and location of benign mucosal polyps and of malignant disease of the colon and rectum. (4) All stages between benign mucosal polyps and carcinoma of the colon and rectum can be demonstrated histologically. (5) Benign mucosal polyps are true tumors and must be considered as premalignant lesions. They are the result of some inherent defect in cellular growth, and not the result of an inflammatory process. (6) A high percentage of the malignant lesions of the colon and rectum originates in preexisting benign mucosal polyps. Therefore, when such premalignant lesions are discovered, they must be removed or destroyed without delay.

If we are to approach the ideal in the treatment of malignant disease of the rectum and colon, which is prevention, there must be a widespread appreciation of this problem by all physicians as well as by surgeons who are performing general diagnostic studies. The purpose of this presentation is to review our knowledge of this subject based on our past experiences at the Lahey Clinic. We have treated a large number of patients with colon and rectal polyps and have recently reviewed in detail a series of 400 patients with this condition treated between 1945 and 1950.

The sizes of the polyps in this series of patients were as follows: 230 were under 0.5 cm. in diameter, 114 were 0.5 to 1.5 cm., and 101 were over 1.5 cm. Four hundred thirty-six were adenomas, and 34 (8%) were papillary adenomas (villous). The incidence of polyps

was greater in the older patients (table 1). Rectal and colon polyps occur much more frequently than has been recognized in the past. At the pathological laboratory of the New England Deaconess Hospital, in the 1,843 consecutive autopsies performed on patients dying between 1935 and 1945 of all causes, benign mucosal polyps of the rectum and colon were found in 7% of the cases. Helwig¹ has found an incidence of 9.5% in an autopsy series of over 1,400 patients. Clinically, we have found polyps in 5% of all patients undergoing sigmoidoscopy who are over 35 years of age, regardless of symptoms. In our autopsy series, polyps were found to be single in 58% of the cases and multiple in 42%. Clinically, polyps have been found to be single in 73% of the patients examined and multiple in 27%. Our studies reveal that 56% of the patients were men and 44% were women.

It has been difficult to estimate accurately the number of patients found to have colon and rectal polyps who have symptoms directly related to these polyps. In our experience the majority of these patients do not complain of bleeding or an alteration in bowel function or abdominal pain, which are the classical symptoms associated with malignant disease of these organs. How, then, since so many patients with rectal and colon polyps do not have symptoms and since polyps occur so frequently, are we to discover lesions of this type? It will be only by the recognition of these facts and by the inclusion of sigmoidoscopic examinations and, on occasion, radiographic studies of the colon for all patients presenting themselves for complete physical examination that we will be able to find benign mucosal polyps of the rectum and colon in large numbers. This has become the policy of the clinic and should be the policy of all physicians doing general diagnostic work. The increase in the number of benign polyps detected in our patients has been in direct proportion to the number of sigmoidoscopic examinations performed, regardless of symptoms.

EXAMINATION

All patients who come to the clinic for a complete physical examination have a careful digital examination of the rectum. A certain number of these patients should be given a sigmoidoscopic examination without preparation. When there has been a recent diarrhea, obvious colitis, a suggestion of some intra-abdominal inflammatory condition, bowel obstruction, or an easily palpable rectal tumor, preparation of the bowel may be contra-

From the Department of Surgery, the Lahey Clinic.

Read before the joint meeting of the Section on Gastroenterology and Proctology and the Section on Pathology and Physiology at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

indicated. When there are no contraindications, however, the patient should be carefully prepared before instrumental and radiographic studies are performed (fig. 2). Castor oil, 1.5 to 2 oz. (45 to 60 cc.), is taken by the patient the night before the examination. On the morning of the examination a careful colonic irrigation is given under trained supervision. The sigmoidoscopic examination may be done a short time after this irrigation. With

Fig. 1.—Surgically removed specimen of rectum showing multiple small, benign mucosal polyps or adenomas, one larger adenoma with a definite pedicle, and an adenocarcinoma.

this method of preparation it must be remembered that adequate suction apparatus must be available at the time of the examination. After a short interval, in order to allow for the evacuation of air that may have accumulated in the colon during the introduction of the sigmoidoscope, satisfactory radiographic studies of the colon can be made. Our technique for the radiographic study of the colon has previously been reported before this section of the American Medical Association. We have made no radical changes in our approach to this problem since that presentation. We still are not completely satisfied with the number of polyps that are being discovered in that portion of the bowel beyond the reach of the 25 cm. sigmoidoscope. The bowel must be completely empty. The examination must be performed by an experienced radiologist. It must be recognized that such examinations are time consuming; they must be performed with special

One of the common errors, which is still noted in our experience, has been the too frequent reliance on radiographic studies of the colon alone for the detection of organic disease of the colon and rectum. To emphasize this problem we conducted sigmoidoscopic examinations in a consecutive series of 150 patients; 15 in this series were found to have benign polyps within reach of the 25 cm. instrument. With this known observation, our radiologists were unable to show the polyps in this area in 10 of these patients. It is imperative that both radiologists and clinicians appreciate this fact and that, when organic disease of the colon and rectum is suspected, a careful sigmoidoscopic examination of the terminal bowel is made before radiographic studies of the colon are performed. In our clinical experience 80% of all benign polyps have been within reach of the usual length sigmoidoscope. In our autopsy experience, however, only 52% were found in this area. Although the average age of the patients in our autopsy series was greater than that of our patients investigated clinically, the figures further emphasize the belief that the accuracy of radiographic examination for detecting colon and rectal polyps is not so satisfactory in many instances as it might be. It is desirable that the usual diagnostic sigmoidoscope become as familiar to students, interns, and examining physicians as the other diagnostic instruments that have been so long in use. The sigmoidoscope should be as familiar to the examining physician as the stethoscope, the vaginal speculum, or the ophthalmoscope.

DIFFERENTIAL DIAGNOSIS

A polyp may be defined as a tumor arising from the mucous membrane of the colon or rectum. There has been no relation, in our experience, between hypertrophied anal papillae, hemorrhoids, or other similar tumors arising from the anal canal, and malignant disease. Polyps may be sessile or pedunculated. The majority are adenomatous in character and should be referred to as ade-

attention to detail, and they are expensive in many instances. At the time of the first examination the usual routine barium enema is given. If contrast air studies are indicated, these are performed, usually at a separate examination and after a separate preparation of the colon. It has been only by the judicious use of both techniques in selected cases that we have been able to find the greatest number of polyps.

Fig. 2.—A, polyp of descending colon, demonstrated by usual barium enema technique. B, same polyp demonstrated by contrast air technique.

nomas. Our pathologists report all benign tumors of this type as mucosal polyps without further differentiation. From a clinical standpoint, however, particular attention must be given to the papillary type of adenoma or the so-called villous tumor because of its marked difference in clinical behavior from the usual adenoma. Such tumors tend to recur locally when incompletely removed and resection should be done if possible. In our 400 pa-

tients, 8% were found to have a benign mucosal polyp of the papillary variety. Sunderland and Binkley² have carefully reviewed the subject of papillary adenomas, and our experience closely parallels theirs. The basic difference between papillomas and adenomas is their manner of growth. The adenoma is a tumor of mucosal glands with little, if any, involvement of the surface epithelium. A papilloma is a tumor primarily of the mucosal surface

Fig. 3.—Papillary adenoma or villous type of tumor of transverse colon.

epithelium with resulting secondary glandular changes and a resulting tendency for growth by lateral spread (fig. 3). It has been our experience that, although fulguration or excision of the adenoma is rarely followed by a recurrence, after the local treatment of the papillary type of tumor, recurrences are almost inevitable unless some type of resection is performed.

The detection and diagnosis of invasive cancer in either the adenomatous or the papillary type of tumors are well understood by surgeons and pathologists who have had extensive experience with this disease. In our experience, however, it is still not uncommon to have patients referred to us with a diagnosis of low grade malignant disease as a result of biopsy and histological examination when, after a careful review of the original slides and further studies of our own, we cannot agree with such a diagnosis. Tumors in which induration, fixation, firmness, or ulceration are evident to the examining finger and to inspection must always be considered malignant. We have previously reported the histological criteria of malignancy in tumors of this type, and these criteria have withstood the test of time. Warren³ has stated that if we accept three important criteria of malignancy—anaplasia, irregularity of architecture, and invasion—it is necessary that at least two of these three factors be present before a diagnosis is made of malignant disease. It is possible for any of these three criteria to be present without actual malignancy with one exception: definite lymphatic or intravascular invasion always means cancer. Meissner,⁴ Warren's associate, has presented certain additional criteria. He has stated, "Cancer must not be diagnosed on the mere presence of numerous mitoses in the tumor. Benign polyps often show many mitoses. The presence of epithelial cells within vessels

often occurs as an artefact produced by cutting the tissue. For the diagnosis of cancer, the intravascular epithelial cells should at least be associated with a thrombus and preferably be actually invading the vessel wall. . . . All portions of the biopsy must be examined before a negative report is made. Otherwise, a small focus of malignant change may be overlooked. The diagnosis of cancer should never be made on borderline evidence. The pathologist should not feel compelled to diagnose tissue that is inadequate. The clinician and pathologist must both appreciate that repeated biopsies may be necessary before a definite decision can be made." It is imperative, when studies of this nature are to be made, that a review be made of the entire tumor together with its base before malignant disease can definitely and finally be excluded.

In our series of 400 patients, 218 tumors were reported as benign mucosal polyps; in 38 patients the report was benign mucosal polyps with early and localized carcinoma; no pathological studies were made in 151 of these cases. (It has been our policy with the very small, clinically benign mucosal polyps to proceed with fulguration without a biopsy.) Benign mucosal polyps were found associated with carcinoma of the rectum in 50 patients, with carcinoma of the colon (fig. 4) in 19, and with non-specific chronic ulcerative colitis in 10 patients.

TREATMENT

We have followed the practice of fulgurizing those polyps that are obviously benign, usually below the peritoneal reflection, that can easily be reached with the sigmoidoscope. These have been fulgurized in many instances, as noted above, without biopsy. To date we

Fig. 4.—Surgically removed specimen of colon showing multiple benign polyps and early adenocarcinoma in ascending colon.

have had no reason to regret this attitude although, as will be further emphasized, it is imperative that these patients be closely observed for an indefinite period of time after such treatment. When a definite pedicle was associated with these polyps, the high-frequency electric snare was used. Ordinarily this type of treatment has been limited to those polyps lying below the peritoneal reflection although, on occasion, when the polyp with its

pedicle and adjacent bowel wall can be clearly visualized, we have not hesitated to remove certain polyps above this area. Obviously, those tumors that have been detected by radiographic studies of the colon and are above the reach of the 25 cm. sigmoidoscope must be removed by the intra-abdominal route (table 2).

One of our principal problems in the treatment of these tumors has been the management of the papillary adenoma, since there is a tendency for these tumors to recur

TABLE 2.—Treatment of 400 Patients with Benign Mucosal Polyps of Colon and Rectum

locally unless some type of resection is performed. Over half of our patients who have had papillary adenomas and who have not had some type of resection have had repeated recurrences, occurring in one patient over a period of 14 years. In three of our patients with papillary adenomas, invasive carcinoma has developed. It has been impossible to predict which of these villous type tumors will ultimately become malignant and which will tend to recur locally. Although we have agreed with Binkley² that, in those tumors that have shown a uniformly benign structure originally and in the earlier recurrences, carcinoma does not tend to develop, our tendency as a result of our experience has been to employ some type of resection for these benign lesions whenever possible. In our entire experience with the fulguration of benign polyps of the rectum, we have only had two instances of perforation. In one of these too much tissue was probably destroyed in a single treatment. In the second instance, perforation occurred after the biopsy of a small, obviously malignant tumor that had been excessively fulgurized in an attempt to control hemorrhage. In both instances immediate resection was successful. It must be noted that, after both biopsy and fulguration of these tumors, hemorrhage can occur and at times require the utmost in experience, skill, and available equipment.

The treatment of those polyps containing localized areas of invasive cancer presents a special problem. It has been our policy in the past that, if it can be demonstrated satisfactorily that the malignant condition has not invaded the pedicle or base of the tumor, that there is no evidence of blood vessel or lymphatic invasion by the cancer, and that the area of malignancy is limited to the periphery of the polyp, complete local excision of the tumor is sufficient. Isolated cases of lymph node involvement have been reported in the literature in cases of this type, but to date this has not occurred in our experience with a series of over 75 cases. It is true that segmental resection of the bowel may be necessary in certain instances for complete histological examination of the polypoid tissue, but we do not agree with those who advocate routine segmental resection for all colon polyps. We definitely believe that, if invasive cancer is found in a polyp and there is

any suggestion that it may have spread beyond the pedicle or into the base, a radical cancer operation should be performed. Polyps, particularly those in the left part of the colon, usually have a long pedicle of normal mucosa. Such polyps can easily be removed by simple colotomy and without bowel resection in most instances. There is general agreement on the treatment of the congenital type of multiple polyposis of the colon. Patients who have this type of polyposis die as a result of malignant disease if their colon and rectum are not removed or all polyps are not destroyed. The oldest patient in our experience lived to 49 years of age before succumbing to cancer. In the past, we have usually treated such patients by surgical removal of the colon and anastomosis of the ileum to the rectum after fulguration of all polypoid tissue in the rectal segment. However, two of our patients have succumbed to malignant disease that developed in the rectal stump. At present we believe that, unless these cases can be followed very closely, the most desirable treatment is removal of both the colon and rectum.

The relation of polypoid disease to chronic ulcerative colitis is receiving increasing attention. It is apparent that cancer of the colon and rectum develops much more commonly in patients who have had chronic ulcerative colitis than in those who do not have this disease. Counsell and Dukes⁵ have recently reported that, in their series, carcinoma of the colon was found in 11% of the surgically removed specimens of chronic ulcerative colitis. Most important, they pointed out that, of those patients who had chronic ulcerative colitis for over 10 years, half of them had associated malignant disease at the time of their surgical treatment. Cattell⁶ has reported from our experience that one in three of our patients who have had chronic ulcerative colitis for over nine years and who have had a colectomy also have had associated cancer. It must be recognized that carcinoma that develops in a patient with chronic ulcerative colitis grows rapidly, metastasizes early, and is malignant to a high degree.

TABLE 3.—Results of Treatment in 400 Patients with Benign Mucosal Polyps of Colon and Rectum

Result	No. of Patients
No recurrence for 5 years or more.....	196
No recurrence for 1 to 5 years.....	150
Subsequent polyps	16*
Subsequent cancer	10*
Death from other causes.....	14
No follow-up	74

* Cases in which polyps or cancer subsequently developed comprised 6% of all cases.

We have attempted to follow 400 patients in our series (table 3) to answer the question: If a patient has a benign mucosal polyp of the rectum or colon and if this polyp is completely destroyed or removed, what are the chances of further polyps or malignant disease developing in these organs? In 6% of the entire series or in 8% of the cases followed, polyps or cancer have developed. Even though the follow-up is incomplete, there is sufficient evidence

5. Counsell, P. B., and Dukes, C. E.: Association of Chronic Ulcerative Colitis and Carcinoma of Rectum and Colon, *Brit. J. Surg.* 39: 485-495 (May) 1952.

6. Cattell, R. B., and Boehme, E. J.: Importance of Malignant Degeneration as Complication of Chronic Ulcerative Colitis, *Gastroenterology* 8: 695-710 (June) 1947.

to indicate that all patients who have had polyps, and most certainly those who have had malignant disease of the colon and rectum, must be followed indefinitely.

Quite a large group of patients come to us for annual complete physical examination. On the basis of our experience to date we do not believe that it is necessary to perform a sigmoidoscopic examination and radiographic study of the colon every year in patients who do not present any colon or rectal symptoms or who have not had any previous organic disease in this area. It is probably adequate to perform such examinations in this group of patients at two year intervals. However, when we have fulgurized polyps without biopsy, it is our policy to give sigmoidoscopic examinations to these patients at the end of six weeks to determine whether the tumor is entirely destroyed and to repeat this examination at the end of three months, again at six months, and annually thereafter. Although we have seen cancer of the colon and

rectum develop without passing through an intermediary polypoid stage, it has been our experience in general that polyps grow relatively slowly.

SUMMARY

1. Data supporting the intimate relationship between benign mucosal polyps of the colon and rectum and cancer are reviewed.
2. The premalignant nature of these tumors is emphasized.
3. Experiences at the Lahey Clinic as to the frequency, methods of detection, differential diagnosis, and treatment of polyps are presented.
4. The importance of the increased use of the sigmoidoscope for the detection of these tumors in all complete physical examinations is stressed.
5. It is suggested that the ideal approach to the treatment of cancer of the colon and rectum is that of prevention. This can be realized by the detection and removal or destruction of these tumors in their premalignant phase.

605 Commonwealth Ave. (15).

UNCOMMON BENIGN LESIONS OF LOWER ESOPHAGUS, DIAPHRAGM, AND CARDIA

Ralph Adams, M.D., Brookline, Mass.

and

Sidney B. Luria, M.D., Waterbury, Conn.

Symptoms occurring from lesions of the lower esophagus and cardia are variable and sometimes difficult to interpret. Patients may believe that they have heart disease, gallstones, cancer of the throat, or duodenal ulcer. Not infrequently, extensive medical studies are carried out to investigate such possibilities before location of the disease process in the esophagus is suspected and proved. Although accurate diagnosis is readily achieved in most cases by careful history and radiological and endoscopic study, any large series of cases will yield a small group of uncommon conditions difficult to diagnose and puzzling to treat. This communication presents six cases with unusual findings.

HEMANGIOMA WITH ULCER IN A FLACCID CARDIA

CASE 1.—A 60-year-old woman had burning, aching, substernal distress of 11 months' duration that was immediately related to food intake. Any hot liquid would cause the distress, and cold liquids had never caused it. She had noticed it with soft foods like mashed potatoes as well as with solid foods like meat. At no time had there been any eructation, regurgitation, or inability to swallow. Her weight had remained constant. By fluoroscopic examination, we saw that the esophagus was wider in the lower fourth, where the barium mixture moved back and forth several times before being expulsively propelled through the cardia into the stomach. A thin collection of the barium mixture was retained just above the cardia, at the upper margin of a tiny diaphragmatic hernia. A gastric diverticulum was seen in the posterior wall of the upper part of the stomach (fig. 1).

At esophagoscopy, a hemangioma, 4 mm. in diameter, was found lying exactly at the junction of the esophagus with the stomach, and in the center of the hemangioma there was a

punctate ulcer. Through a gastroscope, the diverticulum could be visualized, but no other lesion was seen in the stomach. At operation, the hemangioma and ulcer were locally removed. Two 3 mm. mucosal ulcers that had escaped radiological and gastroscopic detection were found high on the lesser curvature of the stomach. They lay at the upper border of the tiny hernia, about 2 cm. superior to the ostium of the diverticulum. They were also locally excised with the diverticulum, and the diaphragmatic hiatus was reconstructed about the cardia to correct herniation. In the six months elapsed since operation, the patient has had no further symptoms.

Recurrent ulceration and scarring may occur in the central portion of any hemangioma subjected to trauma, as is seen in the cutaneous variety located near skin folds or above joints. We have had no previous experience with esophageal hemangioma but were puzzled by the fact that pain was caused by any foods warmer than body temperature but never by cold or iced foods. Such symptoms are contrary to usual observations in lower esophageal inflammatory disease, since nearly all patients with cardiospasm, and many with esophagitis, notice the worst symptoms after taking cold or iced foods. Of course, piping hot liquids will also cause pain in most cases. We have presumed that warm liquids in this case caused dilation of the veins in the hemangioma, with aggravation of symptoms, and that cold foods caused the reverse. We would welcome explanatory comment from others. The two additional ulcers in the gastric mucosa at a flaccid cardia probably contributed to the patient's symptoms, but to an extent impossible to analyze. Except for one patient in whom there was a carcinoma in this region, we have seen no instance in which a small gastric diverticulum arising off the fundus seemed to be of clinical significance.

LOWER ESOPHAGEAL PLAQUE WITH OPEN END VESSEL

CASE 2.—A 65-year-old woman was admitted with a reticulocyte count of 1,500,000 per cubic millimeter, a hemoglobin level of 5 gm. per 100 cc. (photometric method), and a history of frequently recurring melena for five months, together with mild, inconstant, postprandial, high epigastric discomfort. There had been occasional belching but no vomiting. After blood replacement, study with barium showed a small diaphragmatic

Fig. 1.—Hemangioma with ulceration at lower end of esophagus and also a high gastric diverticulum. *A*, anteroposterior projection. *B*, oblique projection, outlining diverticulum.

hernia of hiatus type, just above which there was a tiny, shallow filling defect. Complete gastrointestinal studies were otherwise normal.

At esophagoscopy, a circular, pale white, avascular, firm, fibrous posterior esophageal wall plaque, 6 mm. in diameter, was found just above the esophagogastric junction. In the center of this white, fibrous plaque, there was a reddish brown, punctate point, 1 mm. in diameter, which had the appearance of the end of a small thrombotic blood vessel. As the inner end of the esophagoscope was brought alongside, the vessel began to spurt and the plaque was seen to crack. Further visibility was blocked by escaping blood.

An operation was performed immediately. The esophageal plaque and the bleeding vessel were locally excised and the diaphragmatic hernia repaired. From this procedure, the patient recovered uneventfully, and, when she was seen a month after discharge, she was in good condition with no symptoms and no anemia. Six months later she was seen by her physician because of congestive failure. A nodular liver and a metastatic lesion in a rib were discovered, and she died shortly thereafter. No autopsy was performed, and the primary source of the malignant disease is not known.

Our presumption in this case is that a lower esophageal ulcer had existed previously, with formation of a fibrous scar during periods of recurrent healing, finally followed by erosion into a centrally located vessel within the plaque. The condition would seem almost identical to that of an eroded gastroduodenal branch in a chronic duodenal ulcer base, which one so frequently encounters as a cause of upper gastrointestinal hemorrhage in older ulcer patients. However, we have not seen these conditions in the lower part of the esophagus.

DIAPHRAGMATIC HERNIA SIMULATING CORONARY THROMBOSIS

CASE 3.—A 76-year-old woman had been hospitalized numerous times in the preceding five years with repeated diagnoses of congestive heart failure and coronary thrombosis, after recurring attacks of dyspnea and substernal pressure sensations.

Frequently, she would become ashen gray in color. Oxygen was often required. Electrocardiographic tracings had been interpreted as showing signs of myocardial damage and possible coronary infarction. Her history, however, had never been typical of organic heart disease. The symptoms had always appeared shortly after meals. Although substernal pressure was a prominent complaint, she had never had any actual pain in the chest, nor had there been any radiation into the arms. Walking about or doing any exercise immediately after a meal might cause extreme dyspnea, and sometimes cyanosis, but, four to five hours later, with stomach empty, she could do her housework. There had been no orthopnea.

The patient was obese. The blood pressure was 170/90 mm. Hg. There was a basal soft blowing systolic murmur with a split second sound. An electrocardiogram showed the heart to be regular with rate 70 and rare auricular extrasystoles. The PR interval was 0.16 second, with slurred T_1 , upright T_2 and T_3 , and lowered TV_1 through V_6 . The interpretation was slight left ventricular strain.

There was a huge paraesophageal diaphragmatic hernia. This was repaired, and she was relieved of the symptoms, indicating that they were caused by her large diaphragmatic hernia and food-filled stomach rather than by organic heart disease.

Almost any surgeon with substantial experience in treating diaphragmatic hernia could refer to one or more such cases in his files. On the other hand, this syndrome occurs so seldom in the clinical practice of physicians that it sometimes is forgotten as a source of alarming but peculiar symptoms simulating serious organic heart disease. If not suspected, the diagnosis may be missed because of incomplete symptom analysis. Inability to see the shadow of a stomach herniated into the posterior mediastinum on a plain posteroanterior roentgenogram, often taken as a portable film with the patient in semi-recumbent position because of presumed heart failure, is a second cause of erroneous diagnosis. A third cause is an abnormal electrocardiographic tracing.

PEPTIC ULCER IN A DIAPHRAGMATIC HERNIA

CASE 4.—A 63-year-old man was hospitalized with complaints of hematemesis and tarry stools of three days' duration. The relevant history began with hematemesis four years previ-

Fig. 2.—Large bleeding peptic ulcer in fundus of a stomach herniated through the left diaphragm. *A*, oblique view. *B*, magnification of ulcer crater.

ously. At that time, he was hospitalized, told that he had a duodenal ulcer, and put on a medical regimen. He was asymptomatic until two months previous to admission, when epigastric pain developed that could be temporarily relieved by alkalis. Three days before the patient was admitted, the melena and hematemesis started again. When he was admitted, the

hematocrit was 25% and hemoglobin 8.5 gm. per 100 cc. (photometric method). An upper gastrointestinal tract roentgen examination revealed a hiatus hernia, 9 cm. in diameter, containing an ulcer in the lesser curvature of the herniated portion of the stomach measuring 3.5 by 2 cm. (fig. 2).

Over a period of 72 hours, he was given transfusions of 10 pt. (5,000 cc.) of blood, but he did not stop bleeding. Emergency proximal gastrectomy with esophagogastrostomy and repair of the hiatus hernia was done. His convalescence was uncomplicated, and there has been no further bleeding or pain.

Emergency subtotal gastrectomy has slowly won a well-deserved place in the treatment of massive, persistent hemorrhage from duodenal ulcer. Emergency transthoracic gastrectomy for bleeding ulcer at the cardia is a rarely required procedure, but it was lifesaving for

Fig. 3.—Periesophageal granuloma developed about a tiny diverticulum and causing esophageal obstruction at the cardia. A, spot films. B, oblique view.

this patient. Although not often of exsanguinating proportions, hemorrhage from an ulcer lying within a diaphragmatic hernia is sometimes recurrent and massive. The diagnosis was made by means of an upper gastrointestinal tract examination carried out while there was active bleeding. We believe some lives are lost because such study is withheld when the source of hemorrhage is not already known. To be sure, the most competent of radiologists may not be able to locate the source under such circumstances, even when it subsequently is proved to be from a posterior duodenal ulcer. But oftener it will be located, and the localization will be of inestimable help to the surgeon forced to do an emergency operation for control of upper gastrointestinal tract hemorrhage.

Consider what might have happened without radiological study in the presence of active hemorrhage in the case cited. The patient had been told previously that he had a duodenal ulcer, but there was no sign of such on the roentgenograms or at operation. Basing the approach on statistical chances, with this history, and in the absence of localization by current study, we probably would have done a resection of the distal part of the stomach, pylorus, and proximal duodenum, leaving the intrathoracic gastric ulcer in situ to continue bleeding. The case further illustrates the help to be gained by conducting a portion of the fluoroscopic examination with the patient in the Trendelenburg position.

ESOPHAGEAL GRANULOMA SIMULATING CARCINOMA

CASE 5.—A 44-year-old man was admitted complaining of epigastric and substernal pain of two weeks' duration that was burning in character and occasionally radiated to his back. History revealed that when 5 years old he had swallowed some kind of cleaning fluid used in cleansing of silver. He was in the hospital for an indeterminate period of time and was apparently quite ill. For the succeeding 10 years he had difficulty in swallowing solid foods, but this factor gradually improved except for a feeling of epigastric fullness occurring anywhere from daily to once a month. In 1942, while in the Army, he had repeated roentgen examinations and several series of upper gastrointestinal tests and was told there was nothing wrong except gastritis. Five years previous to admission, he had again noticed epigastric distress occurring immediately after eating, lasting for several hours, and unresponsive to any type of treatment. It then spontaneously improved. Two weeks before admission, dull, chronic discomfort had become more intense and developed into fairly severe pain. Difficulty in swallowing reappeared, and thereafter, until time of admission, he lost over a pound a day, for a total weight loss of 15 lb. (6.8 kg.).

When he was admitted, a series of upper gastrointestinal studies showed dilatation of the mid esophagus with stricture formation in the distal third, the lesion being apparently intramural and extramucosal. A narrowed channel with an ulcerated area, measuring 1.5 cm., was seen on the right posterior wall of the lower esophagus (fig. 3). This finding was confirmed by esophagoscopy. The pathological diagnosis of the biopsy specimen was chronic inflammation.

At operation, a mass was found, involving the distal third of the esophagus and the upper portion of the stomach and measuring 8 by 4 cm. This lesion was resected, and an esophagogastrostomy was done at about the level of the hilus of the lung. Pathological examination showed an inflamed, tiny diverticulum of the lower esophagus with chronic, suppurative, granulomatous periesophagitis.

Although diverticulitis, actinomycosis, and esophageal ulcer were considered in the differential diagnosis, we believed before the operation that the probable diagnosis was carcinoma. At completion of the operative procedure, we felt that the pathological process had been successfully removed but were uncertain as to its morphology. We suppose the intramural granuloma may have developed from infection in a tiny traction diverticulum, the latter having occurred subsequent to ingestion of a chemical in childhood. However, it is a type of intramural extramucosal lesion concerning which we have had no previous knowledge or experience, and which we have been unable to find described.

HUGE ULCER AT CARDIA INVADING PANCREAS

CASE 6.—A 77-year-old woman had been examined 14 months previously because of weight loss and epigastric pain. A large gastric ulcer was found on the lesser curvature of the upper third of the stomach. A regimen of medical therapy for the ulcer was followed by temporary symptomatic improve-

ment. For the preceding three months, she had been failing steadily, with lack of appetite, progressive weight loss, increasing constipation, and upper lumbar back pain.

On admission, she was emaciated, with weight of 80 lb. (36.3 kg.). All viscera were palpable through the thin abdominal wall. By roentgenologic study, a large fixed irregular mass and ulcer were found in the fundus of the stomach, extending along the posterior wall on the lesser curvature side (fig. 4).

The clinical impression was that the patient had carcinoma of the stomach with extension and nodal metastases, and exploration was done only because of faint hope that this impression was wrong. A total gastrectomy was done on Jan. 30, 1951. The spleen and distal half of the pancreas into which the lesion had penetrated were also removed. She withstood this procedure surprisingly well. Pathological examination showed the lesion to be a huge peptic ulcer without malignant degeneration. The patient is still alive, eats a normal diet, and is doing her own housework.

This is the third case, over a period of six years, in which we have done a total gastrectomy for what appeared to be advanced carcinoma and had the lesion subsequently proved benign by microscopic examination. In the same period, we have also had two cases in which

Fig. 4.—Huge high posterior wall gastric ulcer invading the pancreas and found to be benign and resectable. A, oblique projection of stomach. B, tangential projection of ulcer shadow.

cancer was found by microscopic examination of serial sections through the base of small, locally resected, high lesions of the lesser curvature that appeared grossly benign at the time of operation. One of the two lesions was considered benign after study of a frozen section.

That the three patients in whom total resection was performed for ulcer have done well does not change the fact that subtotal resection might have been done more easily, with less risk of fatality and morbidity and with better prospect of subsequent gastrointestinal function satisfactory to the patient. Also, it is poor comfort to the surgeon who has locally removed a small cancer of the lesser curvature that looked like an ulcer to remember that he would have been right in using this therapy for almost all such cases. It is disturbing to the patient to be told a few days later that he must now have another more radical operation that offers less chance for cure than wide resection performed initially. The dilemma that we occasionally face is that of overextensive or too radical surgery for the benign ulcer and improper or inadequate surgery for the carcinoma.

Aside from mechanical leakage or recurrence, two types of late complications may mar the course of a patient who has had a proximal gastrectomy and esophagogastrostomy or total gastrectomy and esophagojejunostomy. These are stricture and severe esophagitis. There are three causes for these complications: tension, failure to establish mucosa-to-mucosa healing, and reflux of secretions. Technical changes and improvements have practically eliminated stricture and severe esophagitis as complications. Esophagogastrostomies function better if created through the cut end, or a separate circular opening, rather than through a slit made in the wall of the stomach. In theory, an enteroenterostomy below an esophagojejunostomy will prevent esophagitis caused by the bathing of the esophagus with duodenojejunal secretions. The theory is unsound in view of the physiological fact that intestinal secretions will always flow along the bowel lumen, if it is unobstructed, rather than through a bypass. A Roux Y-formed anastomosis is the physiologically sound method of doing an esophagojejunostomy and jejunojejunostomy, in our opinion.

SUMMARY

A variety of infrequent pathological processes occurring about the lower esophagus, diaphragm, and cardia are described. One of these is a lower esophageal hemangioma with a central ulcer. Recurrent severe blood loss from a partially thrombosed vessel in a fibrotic lower esophageal plaque, diaphragmatic hernia masquerading as coronary heart disease, and exsanguinating hemorrhage from a peptic ulcer in the herniated fundus are discussed in brief case reports. A rare example of periesophageal granuloma is described, and a huge invasive fundal ulcer causing obstruction and pain and mistaken for malignant disease is reported and analyzed. Diagnosis and treatment of these conditions are recorded. Observations are included on methods of preventing esophagitis as a postoperative complication.

1152 Beacon St. (Dr. Adams).

Golden Jubilee of Discovery of Sleeping Sickness.—In a paper dated April 5, 1903 (Entebbe, Uganda) received by the Royal Society on May 8, 1903, Castellani announced the discovery of trypanosomes in the cerebro-spinal fluid taken during life from natives suffering from sleeping sickness. Up to this time, it was not suspected that sleeping sickness was a trypanosome infection. Castellani observed them on Nov. 12, 1902 but did not make any publication on the subject until after the arrival of Bruce and Nabarro on March 16, 1903. Bruce and Nabarro then showed that the blood, as well as the cerebro-spinal fluid of sleeping sickness cases contained trypanosomes and that so-called cases of trypanosoma fever described by Forde (1902) in West Africa were cases of sleeping sickness in the early stage. In 1904, Mott suggested the examination of the contents of lymphatic glands for trypanosomes. Greig and Gray (1904) stated that trypanosomes were practically always present in the glands of an infected person. They examined sixty-two patients at various stages and found trypanosomes in every one. . . . To Bruce (1903) and his colleagues . . . we owe the demonstration of the fact that the trypanosomes are transmitted from the sick to the healthy by a species of tsetse fly, *Glossina palpalis*.—M. A. Soltys, Golden Jubilee of the Discovery of Sleeping Sickness in East Africa, *East African Medical Journal*, September, 1953.

PENETRATING CRANIOCEREBRAL TRAUMA

OBSERVATIONS IN KOREAN WAR

Arnold M. Meirowsky, M.D., Nashville, Tenn.

In the spring offensive in 1951 in Korea, a 19-year-old U. S. Marine corporal was struck in the back of the head and neck by an unidentified missile. On admission to the First Neurosurgical Detachment he was comatose and did not give any signs of recognition or response. Widely dilated, staring pupils, which did react to light, and fixation of the eyes in left inferior conjugate deviation gave him an almost lifeless appearance. His neck was hyperextended. His legs were flaccid and motionless. Deep tendon reflexes and plantar responses could not be elicited in the lower extremities. There were a few purposeless movements of the left arm and irregular tonic contractions of the right arm. The blood pressure was 140/90 mm. Hg. The pulse was thready and irregular; the rate was 120 per minute. Respiratory excursions were shallow and irregular; the rate was 52 per minute. Examination of the head revealed a huge, gaping, and grossly contaminated laceration reaching from theinion to the midportion of the neck. After a 24 hour period during which oxygen was administered and whole blood transfusions were given, the vital signs stabilized except for the respiratory rate that remained at 52 per minute. Neurological signs were suggestive of severe compression of brain stem and mesencephalon with possible damage to the posterior third of the superior sagittal sinus. For that reason operative intervention was decided on, despite the seemingly grave prognosis. At operation, extensive comminution and depression of the occipital and suboccipital bones were encountered. A large bone fragment had torn the torcular Herophili. The tear extended into the superior longitudinal sinus, which was gaping, and into both transverse sinuses. The lacerated portions of the venous sinuses and the torcular were thrombosed. Repair was accomplished with absorbable gelatin sponges (Gelfoam). Because of the precarious condition of the patient, resection of the cerebellar hemisphere was postponed for a second procedure.

Extraocular movements returned four hours after operation. There was some recovery of motor power in the right leg and in both arms within four days, during which time the patient began to respond but seemed to be blind. After one week, he was fully oriented. In a second operation, a subtotal resection of the right, and a partial resection of the left, cerebellar hemisphere was performed. The patient continued to improve and started walking in a walker three weeks after being wounded. At the time of his return to the States, he still had considerable motor weakness affecting the right arm and left leg. Vision had remained poor, but he could count fingers with either eye at a distance of 4 ft. (121.92 cm.). Two years later this patient was reexamined by Dr.

Charles E. Brackett, Division of Neurosurgery, University of Kansas, Medical Center, Kansas City, Kan. Dr. Brackett said, "The patient is in excellent health at the present time. He is employed as mimeograph operator. He walks with no limp and has noted only slight clumsiness of the right hand. He is not able to see well enough to read print. However, his vision is serviceable for getting about. He is completely free of headaches, dizziness, or any other complaints referable to the central nervous system. His gait is normal except for slightly decreased associated movements of right arm. Station is normal. Romberg sign is not elicited. Succession movements are slightly diminished in right hand. There is slight hesitancy in finger to nose test on the right side. Other cerebellar tests are normal. There is reduced sensation to all stimuli in left leg below groin, but no evidence of muscle weakness. Reflexes are slightly hyperactive in arms, normally active in knees, and hyperactive in ankles, but equal bilaterally. No abnormal reflexes. There is right homonymous hemianopia with macular sparing and a moderate degree of optic atrophy bilaterally. There is no venous engorgement. Extraocular movements are normal. The defect over the torcular is smooth. Some pulsation is noted in the wound that appears to be entirely well healed. Electroencephalogram is normal."

It used to be the general consensus that once a man was shot in the head all powers would be lost except those of vegetation. The preceding story points to the fallacy of such a conclusion, which could readily lead to a "do nothing" policy. The teachings of Harvey Cushing and of some of the most outstanding neurosurgeons in the European and African theaters in World War II have been confirmed again in the Korean campaign. Earliest possible definitive neurosurgical intervention is the single most pertinent factor in the successful treatment of penetrating craniocerebral trauma. Simultaneously available and carefully applied specialized nursing care will prevent many of the complications that may kill outright a man with a penetrating wound of the brain.

RELIEF FROM HEMATOMA

Rapid relief from the damaging effect of hematoma associated with a missile wound of the brain is an important factor in the reduction of mortality. The story of a 25-year-old Canadian infantryman may serve to illustrate that point. He was wounded in action by a booby trap explosion on Dec. 3, 1951. He sustained a penetrating wound of the left temporal area and was taken to the Third Neurosurgical Detachment by helicopter directly from the Battalion Aid Station. On admission he appeared restless and semistuporous but could be roused. He showed moderate weakness of right arm and leg, but there was no inequality of the reflexes. Examination of the head revealed a small circular wound of entry in the left temporal area. The blood pressure was 122/64 mm. Hg. The pulse rate was 68 per minute. The respiratory

Former Neurosurgical Consultant to the Chief Surgeon, Far East Command, U. S. Army.

Presented at the Postgraduate Course on Trauma of the Central Nervous System at the 38th Annual Clinical Congress of the American College of Surgeons, Sept. 22-26, 1952, New York.

rate was 16 per minute. Because of clinical evidence of a rapidly expanding intracranial lesion in the presence of a low velocity wound, it was felt that the man might have an intracranial hematoma, and he was, therefore, given operative priority. The missile tract was found to contain a tremendously large, intracerebral hematoma. There was also a moderately large subdural hematoma covering the greater portion of the convexity of the left frontal and temporal lobes. Inspection of the missile tract after removal of the clot revealed numerous comminuted pieces of bone within the tract; these pieces were removed. There was also a tear in the temporal horn of the left lateral ventricle. Twenty-three days after being wounded, this man was returned to Canada without any neurological deficit.

Through the courtesy of Brig. Gen. W. L. Coke, Director General, Medical Services, Department of National Defense, Canadian Army, I received follow-up notes on this patient. He does not have any neurological deficit. The electroencephalogram shows evidence of slight residual cerebral damage in the left temporal region, spreading at times to the left parieto-occipital region. In a personal letter to me, written 19 months after he was wounded, the patient related that he does not have any headaches or other subjective complaints. He has full use of arms and legs and is employed.

Statistics obtained in rear installations never suggested the frequency with which hematomas occur in association with penetrating wounds of the brain. In a forward area almost half of these casualties proved to have intracranial hematomas, many of which were expanding lesions not compatible with life unless drained without delay.

USE OF ANTIBIOTICS

The tantamount availability of antibiotics in the Korean campaign has been of importance in the reduction of meningocerebral infection. Their real value lies in the combination of antibiotics with early and radical surgery. Partial débridement, retained bone fragments, and retained necrotic tissue and clots may readily give rise to infection despite the use of antibiotics. The history of a 20-year-old American private illustrates this point. He sustained a penetrating wound of the left occipital area during the early days of the Korean campaign. Débridement and closure were performed in an unidentified installation. It was indicated on the patient's record that he had received antibiotics since the day on which he had been wounded. He remained disoriented, was considered to be psychotic, and was admitted to a psychiatric center. There meningitis developed but responded to chlortetracycline (Aureomycin). Two subsequent bouts of meningitis were also treated with chlortetracycline. The patient was seen in neurosurgical consultation after recovering from his last attack of meningitis. The patient appeared to be rational, well oriented, and free from any evidence of systemic infection. Except for a homonymous hemianopia, there was no neurological deficit. Skull films revealed the presence of 11 comminuted bone fragments within the left occipital lobe. At craniotomy, necrotic and partially liquefied brain tissue and numerous retained pieces of bone were encountered. One of these fragments had pierced the wall of the posterior horn of the left lateral ventricle and lay partially within the ventricle. This

piece of bone was surrounded by a small distinct abscess, which fully explained the intermittent bouts of meningitis. The abscess was excised together with the posterior horn of the left lateral ventricle. The left occipital lobe was resected and primary closure performed. The patient made an uneventful recovery and had no recurrence of meningitis.

MANAGEMENT OF SCALP WOUNDS

Harvey Cushing was the first to stress the importance of careful surgical management of every scalp wound. On the basis of his experiences in World War I, he related the high incidence of cortical abnormality in the presence of scalp wounds without bone damage. The tangential bullet wounds of the scalp are but one striking example for this type of abnormality.

This is well illustrated by the story of a 20-year-old Marine sergeant who sustained a superficial scalp laceration on the left side of the forehead in the Okinawa campaign. The laceration was caused by a tangential bullet wound. He had not been unconscious and was admitted to the minor surgery section of an advanced field hospital. The scalp laceration was not débrided, but simply dusted with sulfonamide powder and pulled together with an adhesive strip. Twenty-four hours later the patient began to vomit, complained of severe headache, and became increasingly drowsy. When seen the next day, he could barely be aroused from his stupor. He understood questions, but answered hesitantly and with incorrect and slurred pronunciation. The scalp laceration in the left frontal area was grossly infected. The left pupil was dilated. There was bilateral papilledema and right hemiparesis. Roentgenograms did not show a fracture. The necessary operation, which was made hazardous by the grossly infected scalp laceration, revealed an extradural and a subdural hematoma over the cerebral hemisphere. The craniotomy wound healed in four days; the scalp laceration in four weeks. Radical débridement and layer closure of the wound initially would have prevented the threat of meningitis and brain abscess.

Specific techniques may have to be employed in the treatment of individual brain wounds. The minute details of their general management are essentially the same. Application of these principles is oftener than not the decisive factor in the morbidity and mortality.

GENERAL MEASURES

Initial Examination.—Inspection of the head and a brief neurological examination will suffice to rule out a simple laceration of the scalp without associated intracranial damage. The neurological examination should include a check of the pupils, the visual fields by confrontation, the function of the seventh cranial nerve, motor power, and reflexes.

Roentgenograms.—Roentgenograms should be available prior to craniectomy. These films will give information about the bony defect, number and location of indriven bone fragments, and location of any metallic fragments. Retained bone fragments are the commonest single cause of post-traumatic brain abscess. Postoperative skull films should be made to rule out the retention of isolated bone fragments. If the pineal body is calcified, its position might reveal a subdural or extradural clot that

is not infrequently associated with a penetrating wound of the brain. In the postoperative films, determination of its position will serve to reveal, or to rule out, the presence of a secondary hematoma.

Initial Wound Care.—Initially a wide area about the site of penetration should be shaved and the scalp thoroughly cleaned. A dressing consisting of dry gauze squares and a bandage should then be applied. The use of adhesive bandage on the head can usually be avoided. In fungating wounds, with brain tissue presenting at the surface of the scalp, gauze fluffs may be used, and care should be taken not to apply the bandage too tightly. Débridement of the superficial layers of the scalp, an integral part of definitive surgery, is deferred until such can be effected. Prior to craniectomy, the entire head is shaved and well washed with soap and water for 10 minutes.

To prevent aspiration of mucus and vomitus and to facilitate drainage, comatose patient should be placed on his side with hips and knees flexed, the dependent arm behind the back, the chest supported by a blanket roll, and the head slightly anteflexed but aligned with the spine; A, the position from in front and, B, from behind.

Coma.—Because of existing intracranial tension, patients with penetrating craniocerebral trauma exhibit various degrees of depression of mental alertness. An expanding intracranial lesion may make a patient stupor, semicomatose, or comatose. Other signs and symptoms that may be seen are restlessness, nausea, vomiting, incontinence, bradycardia, hypertension, depression, and irregularity of respiratory rate. In the preoperative and postoperative management of the comatose patient, the following considerations are of vital importance: 1. Free air passages must be maintained. Mechanical obstruction of the air passages is a common cause of early death in the presence of coma. Such obstruction can be overcome and prevented by frequent intratracheal suction and by positioning of the patient. Intratracheal suction will rid the airways of mucus plugs. More important yet is the proper positioning of the comatose patient; this is designed to facilitate drainage and to prevent aspiration of mucus and vomitus. It is inadvisable to keep a comatose patient flat on his back. The most effective position consists of placing the patient on his side with hips and

knees flexed, the dependent arm behind the back, the chest supported by a blanket roll, and the head slightly anteflexed but aligned with the spine (see figure). In such a position, mucus and vomitus cannot be aspirated into the bronchial tree. In order to oxygenate each lung to an equal extent, the patient must be turned from right to left coma position at least every two hours. 2. Blood should be replaced and fluid maintained. Whole blood should be administered intravenously whenever the red blood cell count is below 4 million and the hemoglobin level below 14 gm. The patient should be maintained in a normal state of hydration. An average of 2,500 cc. of fluid every 24 hours is usually adequate. In the event that this fluid has to be administered intravenously, sodium chloride solution should not be used in more than 1,000 cc. of the 24 hour total. 3. Urinary output should be maintained. Many comatose patients are incontinent for urine. A certain number of patients with craniocerebral trauma, however, may have urinary retention for which all of them must be examined. If it is present, catheterization is in order and should be repeated every eight hours. Restlessness, though commonly caused by an expanding intracranial lesion, may be due to bladder distention in the unconscious patient.

A practical method of caring for the incontinent patient was first used during the Okinawa campaign and has again proved its expedience in the Korean War. The patient is fitted with a condom, the tip of which is attached to a tube leading into a bottle on the floor. This prevents the soiling of blankets and sheets and protects the patient's skin from exposure to urine.

Other measures are important in the management of prolonged coma. Special skin care and frequent turning are necessary to prevent decubital ulcers. Spontaneous bowel movements should be prevented by regular enemas since straining may lead to secondary intracranial hemorrhage. Oxygen should be administered in the presence of cyanosis. False teeth should be removed. A padded tongue depressor should be attached to the patient's bed so as to be available in case of a seizure.

Antibiotics and Chemotherapy.—Prophylactic administration of 600,000 units of penicillin and 0.5 gm. streptomycin twice daily to every patient with penetrating craniocerebral trauma is advisable. Such antibiotics as chlortetracycline, chloramphenicol (Chloromycetin), and oxytetracycline (Terramycin) might well be held in reserve for the treatment of specific infections.

Sedatives and Analgesics.—The use of sedatives and analgesics in the presence of craniocerebral trauma is contraindicated for three reasons: 1. Those agents that are sufficiently potent to produce sedation and to relieve pain have a tendency to interfere with intracranial dynamics and to depress respiration. 2. All sedatives and analgesics have a masking effect. Any one of them may impede the establishment of indications for neurosurgical intervention. 3. The narcotic effects of these drugs may delay early surgery and may thus contribute to the degree of irreparable loss of function. In depriving the patient temporarily of rest and of relief from pain, it should be understood that restlessness and irrationalism are the direct sequelae of the expansion of a space-occupying intracranial lesion. This condition can be relieved only by

surgical intervention. Sedatives may begin a vicious circle of increasing the pressure by deepening the coma and of increasing rather than relieving restlessness. Increased intracranial pressure also depresses the respiratory rate. Morphine, for instance, has a similar effect on the respiratory rate that may be embarrassed catastrophically by the combination of the two factors. The irrational, stuporous, or comatose patient is not sufficiently aware of pain to require relief. The conscious patient with penetrating craniocerebral trauma who complains of headache should be reassured and told why his headache cannot be relieved until the necessary surgery has been performed.

SPECIAL MEASURES

Scalp Laceration.—The devastating sequelae of improperly treated scalp lacerations necessitate rigid adherence to neurosurgical operative methods. Secondary infection of a scalp laceration may lead to subgaleal abscess, to osteomyelitis, and to intracranial infection. Immediate débridement and primary closure of a scalp laceration are also necessary because of the possibility of delayed appearance of a neurological deficit, necessitating neurosurgical intervention. An expedient method of surgical repair of a scalp laceration includes (a) shave wide area surrounding laceration, (b) cleanse skin surrounding laceration with soap and water for five minutes, (c) prepare skin surrounding laceration with two coats of thimerosal and two coats of alcohol, (d) drape with sterile towels, (e) excise entire skin edge with scalpel, (f) resect all layers of the scalp within the exposed area, including the periosteum, (g) irrigate wound thoroughly with warm sodium chloride solution, (h) close galea with interrupted sutures of 00 nonabsorbable surgical suture, (i) close skin without drainage with interrupted sutures of 0000 nonabsorbable surgical suture, (j) apply gauze dressing with collodion, and (k) remove skin sutures after 48 to 72 hours.

Compound Fracture of the Skull.—Compound linear fractures without depression, in the absence of a neurological deficit suggesting intracranial damage, may be treated surgically like a scalp laceration. Compound fractures of the base of the skull, as evidenced by a cerebrospinal fluid fistula, may be treated conservatively for approximately 10 days, as long as antibiotics are administered prophylactically. If a fistula does not close spontaneously by that time, surgical closure must be performed. The intradural approach with facia closure of the dural defect is the method of choice. Compound fractures of the vault require immediate craniectomy with débridement of the scalp as previously described and with removal of all depressed and comminuted bone fragments. The dura is opened routinely so as not to overlook the commonly associated subdural hematoma or hydroma or an intracerebral hematoma. The dura is then closed with interrupted sutures of 0000 nonabsorbable surgical suture. The scalp is closed by layers with interrupted sutures of 00 nonabsorbable surgical suture for the galea and 0000 for the skin. No drain is used.

Penetrating Wounds of the Brain.—This group includes all compound craniocerebral injuries with dural penetration. Represented in it are unilateral and bilateral injuries and tangential wounds, as well as through and

through wounds. They may be complicated by a ventricular tear, by laceration of a major blood sinus, or by involvement of an air sinus. As long as definitive neurosurgery can be done early and adequately, even the transventricular wounds and those involving major blood sinus have a high recovery rate. Discussion of the technical details involved in the operative management of the variations of penetrating craniocerebral trauma does not come within the scope of this paper. Their successful treatment consists of early definitive neurosurgical intervention, followed by alert, careful postoperative care. Repair of the bony defect by tantalum cranioplasty should not be done until six months have elapsed. Whenever the wound has been infected at one time or the other, tantalum cranioplasty should be postponed for 12 months.

KOREAN WAR EXPERIENCE

The ultimate goal in the treatment of casualties with wounds of the brain is restoration of the greatest possible degree of function and rehabilitation. The achievement of this goal rests with the availability of earliest possible definitive surgical treatment and simultaneously applied specialized nursing care. Recognizing this, the Army Medical Corps used, in the Korean War, mobile neurosurgical teams that were attached to Mobile Army Surgical Hospitals, functioning at division level. Casualties reached these teams by helicopter directly from the Battalion Aid Station within hours after being wounded. The teams were sufficiently staffed and equipped to perform definitive neurosurgery on all casualties with penetrating wounds of the brain and to render simultaneously the special nursing care that is often the key to success.

While the rate of meningocerebral infection following missile wounds of the brain was 41% during the initial phase of the Korean War, that rate dropped to below 1% with the employment of mobile teams at division level. In the initial phase of the Korean War when neurosurgical casualties had to be flown to Tokyo for definitive care, only 7% of all casualties with missile wounds of the brain had clinically significant intracranial hematomas. That figure rose to 28% when neurosurgical casualties were cared for within 24 hours at a rear installation in Korea. Of patients with missile wounds of the brain admitted during a 10 month period to a mobile neurosurgical team in a forward area, 48.6% of the wounds proved to be complicated by the presence of an intracranial hematoma. We surmise that the realization of earliest possible neurosurgical intervention in the Korean War saved the lives of men who could not have stood the trip back to a rear installation.

The employment of helicopters for the rapid and smooth transport of these casualties made the work of mobile neurosurgical teams possible, and the helicopter pilots deserve much credit for their great contribution. The teams themselves were staffed by a small group of very young neurosurgeons who interrupted their resident training to serve in the armed forces. These young surgeons set a record that speaks for itself. They and a small group of Army nurses and enlisted surgical technicians are responsible for the realization and for the success of the Army Medical Corps' new program in behalf of neurosurgical casualties:

SYNDROME SIMULATING COLLAGEN DISEASE CAUSED BY HYDRALAZINE (APRESOLINE)

H. Mitchell Perry Jr., M.D.

and

Henry A. Schroeder, M.D., St. Louis

The continued, combined oral administration of hexamethonium chloride and hydralazine hydrochloride (called hyphex therapy) in adequate doses effectively controls severe and malignant forms of hypertension.¹ Hydralazine (Apresoline) hydrochloride is a highly reactive compound that combines with carbonyl and sulphydryl radicals and has a strong affinity for certain heavy metal ions.² Late reactions to this active chemical agent were, therefore, predicted³; these have taken the form of collagen disease in all stages of severity.⁴ Others have also described the same phenomena,⁵ and one case of pancytopenia has been reported.⁶

Of 211 patients receiving both drugs for 9 to 30 months, definite symptoms due to delayed toxic effects of hydralazine developed in 17 (8.1%). The preceding period of combined medication (hyphex) varied from 2 to 22 months, and the total ingestion of the offending drug ranged from 25 to 350 gm. (table 1). At its mildest the syndrome consisted of arthralgia and laboratory findings usually associated with hepatic abnormality (case 1). In severer forms it simulated acute rheumatoid arthritis (case 2). The fully developed picture was indistinguishable from disseminated lupus erythematosus (case 3).

Normal or nearly normal blood pressure always accompanied and frequently antedated the appearance of the clinical picture (table 1); less well-controlled hypertensive patients were not affected. Arthritis was present in all patients and was usually both early and prominent. It has varied from vague generalized arthralgia to a single hot, red, swollen, tender joint; distal portions of the upper extremities were most consistently involved. Although there was frequently no other evidence of a damaged

liver, such as hepatomegaly, jaundice, or poor excretion of sulfobromophthalein, abnormal cephalin-cholesterol flocculation and thymol turbidity of the serum were noted every time a search was made. These tests may indicate an alteration in plasma protein rather than hepatic involvement.

The 10 next most frequent abnormal findings in order of occurrence were: pyrexia of over 37.5 C in 11 of 17 cases; microcytic or normocytic anemia of 4 million erythrocytes per cubic millimeter or less in 9 of 14; sedimentation rate of 20 mm. per hour or more in 8 of 13; either gross or microscopic hematuria in 8 of 14; skin rashes of various types in 8 of 16; adenopathy in 5 of 16; albuminuria of 1 to 3 + in 4 of 13; hyperglobulinemia of 3 gm. per 100 ml. or more in 4 of 13; leukopenia of less than 3,500 cells per cubic millimeter in 4 of 14; and splenomegaly in 3 of 16 (table 2).

Although lupus erythematosus (LE) cells were found in the blood of only one patient (case 3), in two other patients the disease closely simulated disseminated lupus erythematosus. In all three, therapy with hydralazine was continued without reduction in dosage after the appearance of arthritis. Two patients (cases 16 and 17) whose cases have already been reported⁴ were the first in whom this syndrome developed; moreover they experienced only a fleeting migratory polyarthritis. One patient (case 3) did not return for examination until long after the appearance of joint manifestations. The following three case histories illustrate the varying clinical picture.

REPORT OF CASES

CASE 1.—A 55-year-old man had progressively increasing hypertension for six years, with blood pressure levels as high as 285/140 mm. Hg. Inadequate therapy with hydralazine and hexamethonium chloride was begun in September, 1952. He entered Barnes Hospital two months later complaining of anorexia, constipation, and poor control of hypertension. Physical examination was unremarkable except for blood pressure of 214/110 mm. Hg and cardiomegaly. The hemogram was normal. The urine contained a few red blood cells and rare casts but no albumin. The nonprotein nitrogen level was 18 mg. and total proteins 6.4 gm., with 2.4 gm. of globulin per 100 ml. of plasma. The urinary excretion of intravenously injected phenolsulfonphthalein was 10% in 15 minutes. Cephalin-cholesterol flocculation was negative, and thymol turbidity of the serum was 0.8 unit. At discharge the blood pressure was regulated at an average of 173/94 mm. Hg. His medication varied from none to 500 mg. of hexamethonium chloride, depending on the prevailing level of systolic pressure, and 150 mg. of hydralazine orally five times a day.

For nine months he remained asymptomatic and well controlled on this regimen until in September, 1953, he noted redness, swelling, and tenderness of the external malleolus of one ankle. His blood pressure at this time averaged 154/84. Physical and laboratory examinations were not remarkable save for a thymol turbidity of 15 units and a cephalin-cholesterol flocculation of 4+. On discontinuation of hydralazine, the arthritis completely vanished within 24 hours. In the subsequent two months the patient's blood pressure rose to 192/99

From the Hypertension Division, Department of Internal Medicine, Washington University School of Medicine, and Barnes Hospital.

This study was conducted under a grant-in-aid from the National Heart Institute, United States Public Health Service, the Lasdon Foundation, and Ciba Pharmaceutical Products, Inc., 510 Morris Ave., Summit, N. J.

mm. Hg despite a sevenfold increase in hexamethonium intake and the addition of 500 mg. of rauwolfia (Raudixin) and 2.4 mg. of protoveratrine a day.

CASE 2.—In 1944 at the age of 43, it was found that this patient had a blood pressure of 160/80 mm. Hg and 3+ albuminuria. Immediately after a stroke of apoplexy in 1947, her blood pressure was 200/120. It had risen to 250/140 in October, 1951, when she was admitted to Barnes Hospital for hypophyseal therapy. Hemogram and urinalysis were normal. Renal and cardiac function were good. With 500 mg. of hexamethonium chloride and 50 mg. of hydralazine given orally every four hours, her blood pressure was regulated at approximately 140/90. By July, 1952, it had fallen to 130/70. In August, swelling and tenderness of both hands and ankles developed and increased to the point of complete immobilization.

Physical examination in Barnes Hospital in October revealed generalized adenopathy. The heart was not enlarged. There were no palpable abdominal organs and no objective joint abnormalities. The temperature was 37.8 C and the blood pressure 142/80 mm. Hg. There were 3,900,000 erythrocytes

CASE 3.—After a stroke of apoplexy when she was 38 years old, this patient's systolic pressure was 280 mm. Hg. In the next four years, tinnitus, vertigo, amblyopia, headache, and dyspnea developed; her weight dropped from 224 to 122 lb. (101.6 to 55.3 kg.). On admission to Barnes Hospital in June, 1952, the woman had a blood pressure of 245/160 mm. Hg, mild hemiparesis, an enlarged heart, and ocular fundi with hemorrhages, exudates, and papilledema. There were 3,350,000 red blood cells and 6,600 leukocytes per cubic millimeter of blood. The urine contained 1+ albumin. The nonprotein nitrogen was 34 mg. per 100 ml. of plasma. Urinary excretion of intravenously injected phenolsulfonphthalein was 30% in two hours. Liver function tests were not done, but there were 6.9 gm. of total proteins, with 2.4 gm. of globulin per 100 ml. of plasma.

On discharge from the hospital, her blood pressure was regulated at 173/107 mm. Hg on 0.5 gm. of hydralazine and a maximum of 2.5 gm. of hexamethonium chloride per day, taken orally in divided doses. For a year her blood pressure gradually fell, was well controlled and she was asymptomatic on this regimen with no restriction of activity or diet.

§ Excluding three patients who stopped hypophex completely.

and 8,500 leukocytes per cubic millimeter of blood. The corrected sedimentation rate was 28 mm. per hour. There was 6 gm. of total proteins with a globulin value of 2.3 gm. per 100 ml. of plasma. There was no albuminuria, but the urine contained rare casts. Urinary excretion of intravenously injected phenolsulfonphthalein was 45% in 15 minutes. Two examinations did not reveal lupus erythematosus cells. Until administration of hydralazine was discontinued, the patient's course in the hospital was stormy. A fever as high as 42 C was recorded, and the arthritis persisted. Her temperature fell below 38 C and her symptoms subsided after the drug was omitted. When it was resumed, there was another spike of fever and a recrudescence of joint pain. Biopsy of an axillary lymph node revealed hyperplasia. She was discharged much improved symptomatically but without medication. Her average blood pressure was 150/82 mm. Hg.

Because of relatively poor control, therapy with hydralazine was reinstituted twice in the outpatient department. Each time the woman's blood pressure dropped from approximately 185/115 to 155/80 mm. Hg, but her joints immediately became so painful that use of the drug had to be discontinued. The mean blood pressure on her last eight visits was 180/111. The present medication is 0.15 gm. of rauwolfia a day. Her arthritis has been completely absent for the six months since hydralazine was last taken.

Twelve months after discharge, shaking chills, dysuria, and dark urine developed. Simultaneously anorexia, malaise, slight pedal edema, and polyarthritides appeared. Her blood pressure averaged 144/99 mm. Hg. When she was seen again after two months of arthritis, she had a slight petechial rash on her arms, generalized adenopathy, hepatomegaly, and a palpable spleen. There were 560,000 erythrocytes and 3,380 leukocytes per cubic millimeter of blood. Her urine contained Escherichia coli and 1+ albumin. The thymol turbidity was 11.8 units, and the cephalin-cholesterol flocculation was 4+. There was hyperglobulinemia of 3.1 gm. per 100 ml. The hydralazine dosage was decreased from 0.5 to 0.25 gm. per day, but it was two months before she would return to the hospital. At that time, physical examination and laboratory data were essentially unchanged save that lupus erythematosus cells were found on several occasions in her blood. When administration of hydralazine was stopped, her maximum afternoon temperature, which had varied from 38.6 to 39.4 C, ranged from 37 to 38 C. In the two weeks after therapy was discontinued, she felt generally better, although her fever exceeded 38 C on four occasions. Cortisone was then given with disappearance of pyrexia; however, after six weeks of hospitalization her blood pressure had daily swings from 225/120 to 140/70 mm. Hg with a mean of 164/96. At the time of

discharge she was taking 1,875 mg. of hexamethonium chloride, 1.9 mg. of protoveratrine, and 8 mg. of alseroxylon (Rauwiloid) a day.

In addition to the 17 definite instances of toxicity due to hydralazine, in 8 persons treated with hyphex mild symptoms developed that may have been an incipient form of the same syndrome that was aborted by reducing or stopping administration of hydralazine. All had relatively normal blood pressure and vague malaise with aching joints. No normal cephalin-cholesterol flocculation tests were obtained. Three other patients had atypical clinical pictures including relative normotension. Eleven months after beginning hyphex therapy a 42-year-old white woman had podagra followed by polyarthritis that was diagnosed as gout. She had 8.3 mg. of uric acid per 100 ml. of plasma, and there was a good response to colchicine despite continued hydralazine ingestion. After six months of therapy a 40-year-old white man became icteric and was found to have a total of 4.68 mg. of bilirubin per 100 ml. of serum. His clinical course was that of mild infectious hepatitis that began to regress a week after use of hydralazine was stopped. A cephalin-cholesterol flocculation test was not obtained until nine

The points on the upper line indicate the number of patients who were receiving therapy with hydralazine at a given time. The lower line indicates the number in whom a delayed toxic reaction to the drug had developed by a particular month. The scales are different by a factor of 10. It is perhaps noteworthy that in the four months from October, 1952, to March, 1953, no new cases appeared, whereas during five months this summer beginning with May, 1953, and continuing through September, 12 cases developed.

days after the last dose of hydralazine was taken at which time it was 2 +. After 10 months of treatment, a 64-year-old white man had as his only symptom hypersensitivity from the waist down sufficient to prevent him from walking; a recent cephalin-cholesterol flocculation was 3 +. The data for these eight patients is given in the second part of the tables.

That abnormal cephalin-cholesterol flocculation and thymol turbidity were not ordinarily found during hydralazine administration was demonstrated by doing these tests on 25 asymptomatic patients who had been on full therapy with similar doses of hydralazine for five months to two years. The cephalin-cholesterol flocculation never exceeded 1 +, and only once was the thymol turbidity more than 4 units.

To date the clinical picture has proved rapidly reversible in all but 1 (case 3) of the 15 patients who have reduced or discontinued dosage of hydralazine for more than a month. Symptoms have vanished, while physical and laboratory abnormalities when followed have reverted to their prearthritic state.

COMMENT

The causative role of hydralazine in producing this syndrome is substantiated by the following facts. 1. Symptoms and signs regressed rapidly when the drug was omitted; severe arthritis sometimes disappeared in 24 hours. 2. In five cases, one or two doses of the drug caused high fever and an acute recurrence of joint manifestations. 3. 1-Hydrazino-4-methylphthalazine and 1,4-dihydrazinophthalazine, chemical analogues of hydralazine, caused the same immediate pyrexia and arthritis in one patient (case 12) that hydralazine thrice produced.⁴ 4. The disease became severer (disseminated lupus erythematosus) when administration of hydralazine was continued despite arthralgia, with regression when it was discontinued. 5. The incidence of the syndrome in patients treated has increased rapidly during the past year (figure). That the hexamethonium ion did not influence the syndrome is indicated by its disappearance while this agent was still being taken.

The characteristically elevated cephalin-cholesterol flocculation, the relative normotension, and, when present, the findings compatible with collagen disease serve to separate delayed toxicity from the immediate febrile reactions and mild early transient arthralgias noted with administration of hydralazine.⁴ The condition is easily differentiated from hexamethonium overdosage that in its acute form is characterized by autonomic paralysis and in its chronic form by interstitial pneumonia.⁴ Acute hexamethonium intoxication has been seen only in azotemic patients who became constipated. In this situation, the damaged kidneys could not excrete the additional drug absorbed from the excessive intestinal pool; however, the margin of safety for hexamethonium salts is considerable since the average therapeutic plasma level is a tenth of that required to produce even mild symptoms.^{2b} Of our five clinical cases of chronic hexamethonium reaction, four patients were men, four were Negro, and all had malignant hypertension.⁴ The syndrome reported here usually resembles one of depletion of some necessary substance rather than one of allergic sensitivity to a drug.

The necessity for discontinuing the use of hydralazine in adequately treated patients formerly suffering from severe and malignant forms of hypertension has posed a therapeutic problem that is still unsolved. The substitution of extracts of *Rauwolfia serpentina* has invariably resulted in a return of hypertension, often despite considerable increases of hexamethonium dosage. For instance, two patients (cases 5 and 6) were taking a daily average of more than 0.6 gm. of rauwolfia along with almost doubled doses of hexamethonium chloride when their most recent blood pressures were obtained (table 1). A substitute for hydralazine, with a similar antihumoral action, is essential for continued control of hypertension in those persons who cannot continue to take the drug because of developing collagen disease. Because the reactions have been reversible, they do not develop in all patients, and the hazard of severe and malignant hypertension is real, the use of hydralazine and hexamethonium chloride represents a calculated risk

worth taking when hypertension endangers health. The agent should not, however, be used indiscriminately without adequate follow-up and an awareness of the nature of late toxic reactions.

SUMMARY AND CONCLUSIONS

Hydralazine (Apresoline) hydrachloride continuously administered for the treatment of hypertension for 2 to 22 months has apparently caused collagen disease of various degrees of severity in 17 of 211 patients. The

condition regressed in all patients when the use of the drug was discontinued. Certain tests, usually correlated with hepatic function, are helpful diagnostic aids.

ADDENDUM

Since this report was written, one patient (case 6) died of a ruptured dissecting aortic aneurysm that was not demonstrable when the hypertension had been controlled.

600 S. Kingshighway (10) (Dr. Schroeder).

SOME DIFFICULTIES IN EVALUATING FUNCTIONAL RESULTS AFTER MITRAL COMMISSUROTOMY

Louis A. Soloff, M.D.

and

Jacob Zatuchni, M.D., Philadelphia

Most reports on the so-called functional improvement following mitral commissurotomy have to be taken on faith. The almost universal acceptance of reports of results that defy critical analysis is unique in modern medicine. Everyone recognizes the difficulties in obtaining noteworthy physiological studies often enough in individual instances to permit some type of correlation with the subjective impression of the patient or even of his physician. Yet, these very difficulties should serve to sharpen the critical clinical acumen of the clinician, because mitral commissurotomy is a term that is applied to a group of blind and crude procedures, none of which, in our experience, in a single instance, has destroyed the characteristics of the lesion it purports to attack. The technical accomplishments of this procedure are interpreted by one person—the surgeon. We do not wish, at this time, to enter into a critical analysis of the surgeon's interpretation, but perhaps the surgeon's enthusiasm is best exemplified by his report of the size of the mitral valve in precise terms of millimeters, which is based on the kinesthetic and epicritic sensations of the gloved finger palpating an irregular orifice in three dimensions, larger or smaller than the finger, and always subject to change in size.

Furthermore, mitral stenosis is but one, albeit important, aspect of rheumatic heart disease that lasts for decades and is subject to unpredictable exacerbations and remissions.¹ We believe that only by longitudinal studies of years' duration, before and after surgery, by competent physicians can the salutary effects of mitral commissurotomy be determined. The postoperative interval is still too short for any definite statement to be made concerning the ultimate value of this operation in the treatment of a disease with such a variable clinical picture as mitral stenosis. The reports of so-called functional improvement following mitral commissurotomy represent, at best, short-term results compared to the duration of the natural history of rheumatic fever. Unless one knows at what stage in the natural history of rheumatic fever the operation was done and the details of the difficulties the person had had since the first recognition of his rheumatic fever or rheumatic heart disease, one may not be able to distinguish the effects of surgery from that of a naturally

occurring or medically induced remission. Witness the fact that salicylates have been known for almost 100 years. Yet, the effects of salicylates on this disease are still a matter for lively debate.²

Dyspnea, the most prominent symptom of mitral stenosis, is frequently partly, and at times wholly, due to noncardiac factors,³ the commonest of which is of emotional origin. Even when dyspnea is totally of cardiac origin, its diminution and, indeed, its total abolition may take place in the presence of progressive deterioration of the heart. For, although dyspnea of cardiac origin is a symptom of significant heart disease, it may still be an early sign, in that succeeding signs of right heart failure usually run a protracted course of one or more decades.¹

The lack of public knowledge, in the epistemologic sense, of the surgeon's accomplishments (good, bad, or indifferent), the unpredictable and chronic course of rheumatic heart disease, and the lack of a one to one correlation between dyspnea and the extent of cardiac involvement represent some of the fundamental difficulties in evaluating the so-called functional results of mitral commissurotomy. Our purpose is not to give a final assessment of the value of this operation, which we believe is impossible at this time, but solely to stimulate a more critical attitude in assessing functional improvement, so that mitral commissurotomy can more quickly find its proper place in the management of mitral stenosis.

IMPROVEMENT WITH MEDICAL MANAGEMENT

First, we must emphasize the truism that most persons with mitral stenosis and failure can obtain functional improvement with medical management. Functional improvement may vary from a slight degree, in those with the most extensive disease, to complete abolition of all signs and symptoms of failure in others. The intervals between successive episodes of worsening of the functional status of the heart or frank failure may vary from

weeks to years and rarely to decades. The episodic nature of failure in mitral stenosis is exemplified by the following case:

A 45-year-old woman (referred by Dr. Leon Prince) was admitted to St. Joseph's Hospital on the service of one of us (L. A. S.) in March, 1938, because of increasing heart failure of six weeks' duration. Symptoms of heart failure followed an upper respiratory infection. There was no previous knowledge of heart disease. Physical examination revealed findings typical for mitral stenosis, auricular fibrillation, and failure of both the left and right sides of the heart. With a medical regimen of salt restriction, ingestion of digitalis, and mercurial injections, she lost all signs of failure within four weeks and was discharged on a maintenance dosage of digitalis. She remained compensated until March, 1939, when transient aphasia and a recurrence of heart failure developed. An intensive medical regimen again restored compensation until January, 1940, when failure occurred again in the wake of a respiratory infection. Again, compensation was restored quickly. But, in October, 1940, failure recurred and was persistent, so that she was readmitted to St. Joseph's Hospital; compensation was restored within one month, only to break down again in the next two months, so that she reentered the hospital in January, 1941. After an intensive medical regimen lasting two months, she was discharged and remained compensated with the aid of digitalis for the next five years. In 1946, and again in 1948, she had heart failure and was hospitalized at Temple University Hospital. Since 1948, she has remained compensated, although she voluntarily limits physical activities. She has needed no mercurial injection since 1948. In 1952, she danced on one occasion.

This case illustrates the episodic nature of, and the variable intervals between, bouts of failure in a person with rheumatic heart disease. Had a mitral commissurotomy been done in 1941 or in 1948 and the clinical course remained unchanged, the surgical enthusiast might have ascribed the five-year functional improvement to the operation. Compare the case above with that following:

A 21-year-old man (referred by Dr. Carl Zibelman) was admitted to Temple University Hospital on the service of one of us (L. A. S.) on Aug. 28, 1941, because of reactivation of rheumatic fever, the first attack of which occurred at the age of 7 years. Examination revealed typical mitral stenosis with first degree block. Under medical therapy, he improved and was discharged in six weeks. He has been seen at yearly intervals and was last seen in February, 1953. There has been no recognizable change in his cardiac status since 1941.

These two cases, cited because they represent two common but contrasting variations of the clinical course of rheumatic heart disease, stress an important observation first made by Grant¹⁴ and subsequently abundantly verified, namely, that once the heart has adjusted to a constant load, no further deterioration occurs until another load is added. The statement, which has been repeated often since the advent of mitral commissurotomy, that mitral stenosis is a progressive deteriorating disease owing to the effects of obstruction has, so far as we are aware, no factual basis and is contrary to all studies with which we are familiar on the prognosis of mitral stenosis. Moreover, the unreasonable and inhumane pessimistic practice of recommending operation on the basis of the possibility of sudden death due either to pulmonary edema in a person with compensated rheumatic heart disease or to exsanguinating pulmonary hemorrhage is entirely unjustified, because these events are extremely rare and because the possibility of death following mitral commissurotomy is almost infinitely greater. In our ex-

perience, we have not observed a single instance of sudden death in a person with rheumatic heart disease in the first attack of pulmonary edema. Indeed, we have not had an instance of sudden death due to succeeding attacks of pulmonary edema in the absence of preexisting heart failure. A review of the literature since 1930 discloses only four deaths reported as due to pulmonary hemorrhage related to mitral stenosis.⁴

Deterioration of the heart in mitral stenosis is most commonly saltatory and due to specific precipitating causes. It is almost axiomatic in cardiology that, when failure appears, a precipitating cause should be sought. Prevention or treatment of such causes are an important part of the treatment of failure itself. The more sudden the onset of failure or the more rapid its progress, or both, the more likely is it that a specific factor other than mitral stenosis is operating. Yet, it is just such patients who are most vulnerable to acceptance of surgery.

The prognosis is better if a precipitating cause for failure is found, particularly one that is subject to successful treatment. It is most important that the cardiac status after surgery, if done, be compared to the status of the person at his best, after adequate medical therapy, and not at his worst, during failure before medical treatment was instituted. To judge from the written reports, the problem of precipitating causes of heart failure and the results of preoperative medical therapy have been ignored. The subtle problem of convalescence that has been, at its best, delayed by surgery, is extremely difficult to assess.

Histories taken personally by each of us independently indicate that 41.7% of our patients subjected to mitral commissurotomy had obvious precipitating causes of failure.⁵ The commonest precipitating cause is a respiratory infection. Other causes are (1) excessive physical exertion, (2) pulmonary infarction, (3) paroxysmal rapid heart action, (4) pregnancy, and (5) emotional disturbances. As Sir Thomas Lewis⁶ stated, "A pessimistic attitude produces apprehension, alarm or a constant feeling of insecurity." The implication that the course of rheumatic heart disease is always rapidly downhill and that surgery will reverse this course engenders psychogenic dyspnea that at times cannot be dispelled without operation. Finally, when there is no specific cause for the appearance or intensification of heart failure, a careful search should be made for stigmas of activity of rheumatic fever.

The problem of recognizing the precipitating causes of failure is part of the large problem of the evaluation of the adequacy of the total medical therapy for failure. Obviously, two persons with similar degrees of failure have different outlooks if one has been digitalized and the other not. For the same degree of failure, the poorer the treatment, the better the prognosis, if it is, as yet, not too late to begin adequate therapy. The fact that many persons have improved functionally with a medical regimen initiated in the hospital before operation is, in itself, eloquent testimony of the inadequacy of medical therapy before hospitalization. It is, to say the least, embarrassing to meet a person who has traveled 1,500 miles for a mitral commissurotomy who has never been admonished about his excessive use of salt.

We are not stating that operations should or should not be done after recovery from failure due to a precipitating event or to inadequate medical treatment. We do say that improvement, if any, after surgery is not necessarily due to the operation. Only after long follow-up studies, preferably after observation during a similar stressful period, can one attribute improvement to the operation.

One must, also, be alert to the possibility of unnecessary medical therapy. For instance, we have learned that many persons with mitral stenosis and sinus rhythm who have by medical management alone recovered from failure due to a precipitating event have remained compensated without digitalis for many months. Seven of 10 such persons in our practice who have received a maintenance dose of digitalis from one to over 10 years have now gone 6 months without any evident need for this drug.

PSYCHOGENIC AND ORGANIC FACTORS

The differentiation of psychogenic and organic factors in the production of dyspnea in persons with mitral stenosis may be very difficult. We believe that observations should be made (1) of the constancy of the relationship and of the amount of physical effort to dyspnea, (2) of the circulation time, venous pressure, and other objective evidence of failure, and, most important, (3) of the roentgenologic findings of the heart and lungs. Severe dyspnea in the absence of roentgenologic signs of pulmonary congestion is probably of noncardiac (psychogenic) origin. Psychogenic dyspnea may be self-induced or iatrogenic. The psychotherapeutic effect of a glamorous cardiac operation has been recognized by many conscientious surgeons. In 14 persons operated upon for mitral stenosis, Varco and Baronofsky could do nothing surgically in 4.⁷ Yet, these four had remarkable functional improvement following their sham operations that did not differ, in general, from the improvement seen in those in whom apparent adequate mitral commissurotomy had been done. We have also noted such instances. The following case, chosen because the surgeon did nothing, shows the striking psychotherapeutic effects of surgery.

A 40-year-old woman (referred by Dr. Wolcuff) had gradually reduced her physical activities over the past 10 years so that for the previous 2 years she had been confined to one floor of her home and for most of the day to a chair. A clinical diagnosis of interatrial septal defect was made that was confirmed by catheterization. These studies showed an arterial oxygen content in the superior vena cava of 11.4 vol. %, and in the right atrium of 14.6 vol. %. Because of the tremendous pressure in the pulmonary artery (92/44 mm. Hg), and in the right ventricle (98/10 mm. Hg), an attempt was made to correct the interatrial septal defect surgically but the defect was so large that this was impossible. After a stormy postoperative week, she recovered rapidly and was discharged at the end of the second week. She walked out of the hospital and made a remarkable functional recovery, so that she was able within four weeks to do her own housework. Three months after operation, she asked permission to seek outside employment.

We have already stated that there is no one to one relationship between symptoms and the extent of heart disease. Cardiologists have known for a long time that dyspnea may diminish with the onset of right heart failure or after the appearance of auricular fibrillation that is controlled with digitalis.⁸ Yet, all cardiologists have regarded these events as indications of progression of

cardiac disease farther down the road to its ultimate end. There is no reason, as yet, to regard the surgical production of permanent auricular fibrillation that occurred in our series of 11.1% of persons subjected to mitral commissurotomy as different in its prognostic significance because dyspnea may be less.⁵ Similarly, dyspnea can be diminished by surgical production of embolic phenomena that lead to a restriction of physical and sometimes mental activities. The incidence of these events has been reported as varying from 2.8% in those with sinus rhythm to 13.5% in those with auricular fibrillation.⁹ Cardiac enlargement has also been regarded as a sign of an increased burden on the heart. We see no reason why surgical production of enlargement, seen roentgenographically in 57.7% of our patients followed for as long as 22 months after surgery, should be regarded differently.¹⁰

We leave to the clinical physiologist an evaluation of the validity, the intrapersonal error, the stability, and the noteworthiness of the numerical figures attributed to them by catheterization.¹¹ Some of the mathematical manipulations have been regarded as absurd.¹² As clinicians, we wish to emphasize that, in our opinion, the figures obtained before and after operation cannot be related to the operation itself unless all the clinical data at the time the two studies were done are known. Thus the significance of catheterization data given as isolated reports defies analysis. A drop in pulmonary pressure obtained after operation may be due to the operation, but it may also be due to the medically induced or natural improvement before or after operation but after the preoperative studies. Furthermore, a drop in pulmonary pressure may actually mean a worsening of the cardiac condition, if auricular fibrillation or cardiac enlargement has occurred.¹³ We do not feel that data obtained by catheterization in the immediate postoperative period can be interpreted as showing improvement because, in our experience, the cardiac silhouette at this time is always larger than it was before operation.¹⁰

POSTOPERATIVE MORBIDITY

Lastly, the frequent morbidity, which is usually due to a reactivation of rheumatic fever¹⁴ and occasionally due to surgical production of mitral regurgitation,⁵ makes evaluation of functional improvement difficult. This is so because patients, and indeed their physicians, are so relieved that the patient feels better after the postoperative prolonged illness that they forget the preoperative status and talk in terms of how much better the patient is compared to his postoperative illness. The deceptive and the confused nature of the functional improvement following operation is shown by the following report of a person who is pleased (at the time of writing) with the results of operation.

A 41-year-old woman (referred by Dr. E. Weinberger) first had dyspnea in 1943, after the death of her father. A diagnosis of mitral stenosis was made. Dyspnea disappeared following reassurance. She remained well until December, 1947, when, after a respiratory infection, cough, fever, and recurrent hemoptyses developed. Nine days of medical treatment at Temple University Hospital abolished all symptoms until a recurrence in September, 1949. This time, she remained at the hospital three weeks. In the next year, she admitted to fatigue and slight dyspnea upon climbing steps but received no cardiac medication. In the last week of January, 1953, a mild respiratory infection developed and lasted three weeks. After this, she

had a sharp pain in the region of the left scapula, which she ignored. The next day, she did heavy housework because of the absence of her maid. That evening partial aphasia and pulmonary edema developed. She was admitted to the service of one of us (L. A. S.) at Temple University Hospital. Energetic medical therapy restored compensation within 10 days, after which she walked on the level free of dyspnea and had residual hesitation in speech.

Mitral commissurotomy was finally performed on March 10, 1953. The valve was heavily infiltrated with calcium. As the anterolateral commissure was fractured, the finger lacerated the left ventricular wall. Bleeding was quickly controlled by sutures. No regurgitant jet was palpable after operation, but auricular fibrillation was recognized. The following day a systolic murmur, of grade 2 intensity, was heard for the first time. Dyspnea increased so that on the fourth postoperative day, four pillows were necessary for comfort. Fluid was present in the left pleural cavity. The neck veins bulged, the liver was enlarged to the level of the umbilicus, and the legs were edematous, 4+. She had gained over 12 lb. (5.4 kg.). In addition to an increase in the amount of digitalis, she was placed on salt restriction and was given mercurials, and her chest was tapped. Over the next five weeks, seven pleural taps were necessary, yielding an average of 600 ml. of fluid each. Finally, the chest remained dry and the legs lost their edema. At the time of writing she could walk slowly on the level without dyspnea. She had driven a car and danced slowly.

The so-called functional improvement of this patient after mitral commissurotomy was an illusion based on her recovery from the surgically produced heart failure. She was obviously no better than she was either before or after her attack of pulmonary edema. The physical examination suggested, on the contrary, that she was considerably worse, for she had still at the time of writing bulging neck veins, moderately enlarged liver, a larger heart by roentgenography, auricular fibrillation, and signs suggesting mitral insufficiency plus the mitral stenosis. Subsequent events (increasing physical limitations and intensification of a regimen for cardiac failure) established the illusory nature of the functional improvement.

We have other instances of persons who are elated because of the clinical subsidence of a disabling postoperative reactivation of rheumatic fever. Even, however, in persons fortunate enough not to have postoperative symptom-producing complications, changes in the heart may occur that are ordinarily regarded as deleterious in the presence of so-called functional improvement. We refer to permanent auricular fibrillation, roentgenologic evidence of cardiac enlargement (often overlooked because of surgical removal of the left auricular appendage), and the presence of subclinical right heart failure.

SUMMARY

To be meaningful, reports attributing improvement to mitral commissurotomy should provide evidence that (1) medical and naturally occurring factors were not active and (2) no deleterious effects were produced. Sufficient factual data should be given so that the reader can form his own conclusions. The surgeon's conception of his accomplishment should be included. A correlation of these statements with the so-called functional improvement may help to differentiate psychotherapeutic, naturally occurring, and medically induced remissions from the surgical accomplishments. For instance, Souttar's patient,¹⁵ often cited as the first to have a successful mitral com-

missurotomy, had such gross mitral regurgitation and so little mitral stenosis that nothing was done, and Cutler¹⁶ did what every cardiac surgeon would fear to do, namely, to excise part of the septal leaflet of the mitral valve.

An accurate evaluation of results is extremely important because mitral commissurotomy has an immediate higher mortality (at the very least 6%) for any group than the naturally occurring annual mortality (about 1%) and because its morbidity is very high. The fact that the heart can readjust functionally to the added load imposed on it by surgery should not be permitted to mask the actual effects of the operation.

Broad and Ontario St. (Dr. Soloff).

CLINICAL NOTES

PSEUDOHEMATURIA CAUSED BY PARA-AMINOSALICYLIC ACID, SULFONAMIDES, AND PARA-AMINO BENZOIC ACID

L. B. Horowitz, M.D.

David Salkin, M.D.

and

John Gilrane, M.D., San Fernando, Calif.

In December, 1952, a semiambulatory tuberculosis patient reported to his physician that he voided bloody urine in the toilet bowl on two occasions. Unfortunately, he had already flushed the toilet, but later urinalyses showed no blood or pus chemically or microscopically. Examination of the genitourinary tract, including cystoscopy and pyelography, revealed a bifid left kidney with a double ureter but no lesion to explain the hematuria.

During the next two months, several other patients complained of voiding bloody urine, and this was corroborated by their physician. Although the fluid was not examined, numerous urinalyses on these patients failed to reveal blood, and further detailed studies were contemplated. Questioning of one of the patients, a medical student, disclosed, however, that the urinary stream was colorless but turned blood-red only after it hit the bowl. One of us (J. G.) noted the same phenomenon independently on himself.

Further investigation revealed that all of these patients had voided shortly after the hospital afternoon rest hours (1 to 3 p. m.) and that they were all receiving 1 gm. of streptomycin twice weekly and 15 gm. of sodium *p*-aminosalicylic acid daily. Moreover, the janitorial staff always cleaned the toilets during the rest hours and invariably left a liberal amount of Acme chlorinated lime in the bowl to be flushed by the first user. Studies were made and showed that the blood-red urine was produced by the action of the chlorinated lime on urine containing *p*-aminosalicylic acid, its sodium and calcium salts, and its degradation products. A similar "bloody" reaction

From the Veterans Administration Hospital, San Fernando, Calif.; the Barlow Sanatorium, Los Angeles; and the Department of Medicine, School of Medicine, University of California, Los Angeles.

Henry E. Weimer, Ph.D., and Harold C. Haymond, A.B., gave technical assistance.

occurred when the urine contained sulfonamides or *p*-aminobenzoic acid. No such reaction occurred with the urines of patients not taking these drugs.

MODE OF ACTION

Hypochlorous acid and its salts, the hypochlorites, are unstable and decompose readily to give up oxygen and chlorine. The salts in ordinary commercial use are calcium hypochlorite and sodium hypochlorite and are utilized as bleaches, oxidizers, disinfectants, and decontaminants. Calcium hypochlorite, $\text{Ca}(\text{OCl})_2$, is a dry white powder and is prepared for commercial use as chlorinated lime by passing chlorine over dry calcium hydroxide. The resulting compound is a mixed calcium salt of hypochlorous and hydrochloric acids and has a variable composition of approximately $\text{Ca}(\text{OCl})_2 \cdot \text{CaCl}_2$ with water.¹ It is a white powder that has a strong odor of chlorine, contains about 35% active chlorine, and decomposes on exposure to water or air; most of it is soluble in water or alcohol. Sodium hypochlorite (chlorinated soda) has similar properties and is commercially available in dilute solutions, such as Purex or Clorox, that contain about 5% of available chlorine.

The hypochlorites produce an orange or red color, resembling blood, when mixed with *p*-aminosalicylic acid and its sodium and calcium salts; most of the sulfonamides; *p*-aminobenzoic acid, procaine and the compounds procaine amide and procaine penicillin; butacaine (Butyn) sulfate; and ferric salts. They produce a purple color with aniline, a brown color with histidine, and a green color with succinylsulfathiazole (Sulfasuxidine). However, no color reaction occurs when the hypochlorites are mixed with compounds such as salicylic acid, acetylsalicylic acid, benzoic acid, tyrosine, casein, phenylalanine, tetracaine (Pontocaine), dibucaine (Nupercaine), and benzylamine and well known chemotherapeutic agents such as streptomycin, penicillin, oxytetracycline (Terramycin), chlortetracycline (Aureomycin), chloramphenicol, and isoniazid. Examination of the aromatic compounds mentioned shows that those producing a red color with the hypochlorites have a primary unsubstituted amino group (NH_2) attached directly to the carbon ring. Histidine and succinylsulfathiazole show a substituted arylamine group.

The mode of action of the hypochlorite was explored. No color reaction occurred when *p*-aminosalicylic acid was mixed with acids such as hydrochloric or sulfuric, bases such as sodium or ammonium hydroxide, oxidizing agents such as hydrogen peroxide, reducing agents such as sodium thioglycollate, and cleaning agents such as trisodium phosphate. The ordinary salts of chlorine, bromine, and iodine also failed to produce a color reaction. A red color developed immediately, however, when nascent chlorine was bubbled through a solution of *p*-aminosalicylic acid or sulfanilamide or when bromine water was added. It is felt, therefore, that the hypochlorites act by virtue of their available chlorine.

The chlorine acts on the aromatic primary amines in one of two ways, either by a halogenation process similar to the bromization of aniline² or by the formation of a chloroamide. In the halogenation process, the amino group acts as a powerful agent in affixing the halogen at

all available positions, ortho and meta to itself. In the case of aniline, there is produced a trichloranilin, and similarly there may be produced compounds such as mono-, di-, or trichlor-*p*-aminosalicylic acid. The chloroamide process apparently occurs when a hypochlorite acts on a sulfonamide.³ Either one or both hydrogen atoms are replaced by the chlorine to produce a monochloramide ($\text{N} \cdot \text{H} \cdot \text{Cl}$) or a dichloramide ($\text{N} \cdot \text{Cl} \cdot \text{Cl}$).

A search of the organic chemistry literature provided no definite clue to the exact chemical nature of the organic compounds responsible for the red color. Although Beilstein⁴ and Heilbron and Bunbury⁵ list chlorine derivatives for isomers of *p*-aminosalicylic acid, the chlorine derivatives of the compound itself have not been adequately investigated.

SENSITIVITY

Color development was proportional to some extent to the concentration of the *p*-aminosalicylic acid and calcium hypochlorite. The color intensity was plotted in Klett units and followed Beer's law over a portion of the curve. In aqueous solution, an excess of chlorinated lime produced colors visible to the naked eye at the following levels. Para-aminosalicylic acid showed an orange color at 0.2 to 0.6 mg.; the sulfonamides showed a yellowish color at 3 to 6 mg. and an orange color that deepened on standing at 12 to 20 mg.; sodium *p*-aminobenzoate showed a pale orange color at 0.15 mg; procaine hydrochloride produced a yellow color at 0.2 mg. and an orange color at 0.5 mg.; aniline produced a purplish color at 0.035 mg. and the color became intense at 0.07 mg. The sulfonamides tested include sulfanilamide, sodium sulfathiazole, sodium sulfadiazine, sulfapyridine, and sulfoxazole. Several times these concentrations produced deep red colors resembling blood.

In urine, an excess of chlorinated lime detects *p*-aminosalicylic acid and its degradation products at 2 to 3 mg. so that it can be seen with the naked eye, or about 10 times its concentration in water, chiefly because of the already amber color of the urine. The sulfonamides are detectable in urine at a level of 20 to 30 mg. and sodium *p*-aminobenzoate at an even higher level. Even greater concentrations are necessary to produce the typical blood-red color. When tested against the urines of patients taking *p*-aminosalicylic acid, chlorinated lime produced a blood-red color as early as 30 minutes after ingestion and as late as 14 hours or more. In serum, the standard tests are much more sensitive in detecting the drugs than the chlorinated lime; thus, it cannot replace the current tests for the detection of these compounds.

SUMMARY

The use of commercial preparations containing calcium or sodium hypochlorite as disinfectants in toilet bowls may produce a red color resembling blood on the

addition of urine from patients who are taking *p*-aminosalicylic acid, the sulfonamides, and *p*-aminobenzoic acid. Although the hypochlorites are not so sensitive as the standard tests in detecting these drugs, they may be used as a rapid, cheap, qualitative screening test assuring the physician that the drugs are being taken. One must be aware that under these conditions a pseudo-hematuria may be produced and that it must be differentiated from true hematuria, especially in patients under treatment with sulfonamides.

CHEMICAL LABORATORY

This is the third of several reports on cigarettes, cigarette smoke, and filters by the Chemical Laboratory of the American Medical Association. The first report appeared in THE JOURNAL, July 4, 1953, page 917. It concerned filter tip cigarettes. The second report appeared in THE JOURNAL, July 11, 1953, page 1035. It concerned cigarettes in which the tobacco is claimed to have a low nicotine content.

3. Cigarette Holders

The Chemical Laboratory has examined five brands of cigarette holders that contain filters to determine their efficiency in removing nicotine and tars from cigarette smoke. The methods of analysis and experimental conditions for smoking have been described in a previous report.¹ Briefly, 47 mm. of each cigarette was smoked (two-thirds of a "standard" 70 mm. cigarette) using 35 ml. puffs of two seconds' duration taken once a minute.

A "standard" 70 mm. cigarette, one of the best-selling cigarettes, was used in the smoking experiments. These cigarettes weighed an average of 1.096 gm., were 69.9 mm. long, and had a circumference of 26.5 mm. The moisture content of the tobacco was 11.52% and the tobacco contained 2.08% nicotine on a moisture-free basis. The dry weight of the tobacco actually smoked was 0.631 gm. per cigarette.

Of the cigarette holders examined, both numbers 1 and 2 employ a metal trap like those found in many pipes. Number 3 uses a cylindrical paper filter measuring 56 mm. in length and 6 mm. in diameter and containing a number of small paper baffles. Number 4 uses a plastic cylinder measuring 36 mm. in length and 9 mm. in diameter and filled with granules of silica as a filter. Number 5 uses a cigarette inserted in the holder as the filter.

All cigarette holders tested changed the smoking characteristics of the cigarettes in two ways: First, air leaked in between the cigarette and the holder in all cases and around the ejectors in holders number 4 and 5. This leakage amounted to more than 5% in some individual holders. Second, all the holders used a compression fit to reduce this air leakage. The specially machined Bakelite holders used in this experiment for smoking the comparison cigarettes provided a rather snug fit with an internal diameter of 8.3 mm. (The cigarettes were sealed in these holders with a concentrated dextrose syrup that prevented any air from leaking between the holder and

the cigarette and insured that the entire 35 ml. puff was drawn through the cigarette.) Holder number 1, however, compressed the butt end of the cigarettes to 7.4 and 7.2 mm. and holder number 2 to 7.6 and 7.2 mm.; holders 3, 4, and 5 all compressed the butts to 7.8 mm. diameter.

The results of the experiments are given in the table. The figures in column 1 are obtained by multiplying the average number of puffs required to smoke the cigarette to the 47 mm. mark by the volume of each puff (35 ml.) and represent the average volume of smoke drawn into the absorption train. This mainstream smoke represents the smoke that presumably would reach the smoker's mouth. Column 2 shows the weight of nicotine in this smoke. Column 3 shows the weight of nicotine recovered from the holder and its trap or filter, and represents the nicotine removed from the mainstream smoke as it passes through the holder. Column 4 is the total of columns 2 and 3. The percentage reduction in nicotine in the mainstream effected by the holder is listed in column 5 and is based on the difference between columns 4 and 2.

In columns 6 and 7, the weight of tars appearing in the mainstream smoke per cigarette and the weight of tars recovered from the holder and its trap or filter are given. The

Removal of Nicotine and Tars from Smoke by Cigarette Holders

Column	1	2	3	4	5	6	7	8	9
"Standard" Cigarette	375	2.65		2.65	..	18.2	...	18.2	..
Holder 1	380	2.50	0.13	2.63	5	15.5	1.4	16.9	8
Holder 2	303	2.15	0.10	2.25	4	15.6	1.9	17.5	11
Holder 3	367	2.57	0.20	2.77	7	15.1	1.5	16.6	9
Holder 4	373	2.28	0.37	2.65	14	14.7	3.8	18.5	21
Holder 5	376	1.51	1.05	2.56	41	10.8	...	...	41

totals of these tars are listed in column 8. The percentage reduction in tars in the mainstream effected by the holder is listed in column 9 and is based on the difference between columns 8 and 6.

The tars absorbed by the tobacco in the cigarette used as the filter in holder number 5 could not be recovered. An approximate value for the weight of tars absorbed by holder number 5 may be calculated by assuming that the value for total tars found for the "standard" cigarette may be substituted for the total tars of holder number 5. The weight of the tars that were recovered from holder number 5 may then be calculated by subtracting the weight of tars found in the mainstream smoke (10.8 mg.) from the substituted value (18.2 mg.).

The figures in the table are the averages per single cigarette for runs of the first five cigarettes smoked through a clean holder and filter. The efficiency of most of the holders dropped as additional cigarettes were smoked. When 20 cigarettes were smoked through the holders, number 1 lost 27% of its original effectiveness, number 2 lost 42%, number 3 lost 14%, number 4 lost 34%, and number 5 lost none of its effectiveness.

Holder 5 was found to be the most effective of the filters tested. Holders 1, 2, and 3 were ineffective. The performance of holder 4 was intermediate between that of number 5 and the ineffective group.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

APPARATUS ACCEPTED

The following additional products have been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

RALPH E. DE FOREST, M.D., Secretary.

Maico Maxitone Hearing Aid

The Maico Company, Inc., 21 N. Third St., Minneapolis 1.

The Maico Maxitone Hearing Aid is a three tube instrument powered by one 1.5 volt A-battery of the mercury type and one 15 volt B-battery. The amplifying system is housed in a plastic case that measures 64 by 47 by 22 mm. and weighs 53 gm. The receiver weighs 8 gm., the receiver cord 5 gm., the A-battery 13.5 gm., and the B-battery 12 gm., making a total weight of 91.5 gm.

Evidence indicating good construction and satisfactory performance was obtained from sources acceptable to the Council.

Maico Transist-Ear Hearing Aid, Model O

The Maico Company, Inc., 21 N. Third St., Minneapolis 1.

Maico Transist-Ear Hearing Aid, Model O

The Maico Transist-Ear Hearing Aid, Model O, is a tubeless instrument employing three transistors. The power is furnished by a single 1.5 volt cell of the mercury type. The body of the instrument measures 46 by 64 by 16 mm. and, without battery and receiver attachments, weighs 84 gm. The battery weighs 14 gm., the receiver with its cord weighs 11 gm., making the total weight 109 gm.

The Council obtained evidence indicating that this device

was soundly constructed

Hydromassage Subaqua Therapy Unit, Model HM 1100

Ille Electric Corporation, 50 Mill Rd., Freeport, Long Island, N.Y.

The Hydromassage Subaqua Therapy Unit, Model HM 1100, also referred to as the Combination Hydromassage Treatment and Wading Tank, is a large unit intended to be installed permanently, with connections to the plumbing, in a department of hydrotherapy.

Hydromassage Subaqua Therapy Unit, Model HM 1100

The complete unit consists of a stainless steel tank with a wading trough, adjustable hand rails, stainless steel steps, and body suspension wading harness. Included also are a water stretcher with cross bar and suspensions, canvas body sling, body hammock, head rest and plinth, miscellaneous tank fittings, dial thermometer, thermostatic water mixing valve assembly, two electric turbine ejectors, two turbine ejector carriages, and two turbine ejector elevators. The ejectors require 60 cycle alternating current at 115 volts and draws 1,150 watts.

The apparatus is shipped in two parts: the larger measures 150 by 290 by 213 cm. (60 by 114 by 84 in.) and weighs 680 kg. (1,500 lb.), and the smaller measures 137 by 63 by 63 cm. (54 by 25 by 25 in.) and weighs 227 kg. (500 lb.).

Evidence indicating satisfactory construction and operation was obtained from sources acceptable to the Council.

Telex Hearing Aid, Model 954

Telex, Inc., Telex Park, St. Paul 1, Minn.

The Telex Hearing Aid, Model 954, contains two vacuum tubes and one transistor. It requires one 1.25 volt A-battery and one 30 volt B-battery. Excluding the minor projections, it measures 90 by 44 by 18 mm. The main portion of the instrument weighs 102 gm. The batteries weigh 49 gm., and the earphone with its cord weighs 20 gm., making a total of 171 gm. The Council obtained evidence indicating sound construction and satisfactory performance.

Telex Hearing Aid Model 954

Kegel Perineometer

Perineometer Research Laboratory, Inc., 2007 Wilshire Blvd., Los Angeles 5, Calif.

The Kegel Perineometer is an apparatus for indicating the strength of contraction of certain pelvic and perineal muscles. The apparatus, by providing a wide range of resistances to the contracting muscles, is useful in the training and strengthening of these muscles. It consists of two parts: one is for insertion into the vagina, and the other is an aneroid manometer with a dial reading from zero to 100 mm. Hg. The two parts are connected by a rubber tube.

The part designed for vaginal insertion is made of rubber and shaped roughly like the finger of a glove. It is held rigid by a metal axis that projects to a height of about 9 cm. at right angles from the center of a circular disk that is about 7.5 cm. in diameter. When the rubber chamber is squeezed, the pressure is transmitted through the rubber tube to the manometer and the pressure is easily read.

The apparatus is contained in a case measuring 17 by 9 by 8 cm. (6½ by 3½ by 3¼ in.) and weighing 425 gm. (1 lb.). The shipping weight is 600 gm. (1¼ lb.).

Evidence obtained from sources acceptable to the Council showed that the device was well made and useful for the purpose for which it was intended.

Kegel Perineometer

Otarion Hearing Aid, Model B-30

Otarion, Inc., 4757 Ravenswood Ave., Chicago 40.

The Otarion Hearing Aid, Model B-30, uses three vacuum tubes, one 1.25 volt A-battery, and one 30 volt B-battery. The body of the instrument measures 80 by 45 by 23 mm. and weighs 82.5 gm. The batteries weigh 40 gm., and with earphone and receiver cord the total weight is 134 gm. This model is larger, heavier, and more powerful than the Otarion Hearing Aid, Model B-15.

Evidence indicating satisfactory construction and performance was obtained by the Council.

Otarion Hearing Aid Model B-30

Cable Address "Medic, Chicago"

WHY THE "BRICKER AMENDMENT" IS IMPORTANT TO THE MEDICAL PROFESSION

The controversy stimulated by the amendment to the Constitution proposed by Senator Bricker and 63 of his colleagues has spread to every segment of our population, including the medical profession. The American Medical Association has received a number of letters from physicians during the past few weeks expressing various sentiments concerning the proposal. Some endorse the amendment wholeheartedly; others have deplored the intervention of organized medicine in what they consider to be a nonmedical issue; still others have requested additional information defining the threat to our system of medical care posed by our present method of negotiating and ratifying treaties.

On January 7, 1953, Senator Bricker and 63 co-sponsors introduced S. J. Res. 1, 83rd Congress, which proposed the adoption of a constitutional amendment limiting the treaty-making authority. This resolution was referred to the Senate Judiciary Committee together with S. J. Res. 43 (sponsored by the American Bar Association). On June 15, 1953, the committee submitted a favorable report on S. J. Res. 1, with amendments, and recommended that it be adopted. The amended version of the resolution, as approved by the committee, stipulated that any provision of a treaty that violated the Constitution would be invalid and that the treaty power could be used to establish or modify internal law in the United States only through the enactment of domestic legislation that could have been adopted in the absence of such treaty.

In tracing the interest of the medical profession in the Bricker amendment, it is important first to recognize the fact that treaties become the supreme law of the land if ratified by two-thirds of the Senate present and voting. In addition, it must be noted that significant changes have occurred during the past few years in the scope of treaties and executive agreements negotiated by the executive branch of the government. Although these instru-

ments formerly involved only international matters, there are now pending treaties or executive agreements whose ratification would change our domestic laws.

In the health field three specific situations can be explored. They deal with the activities of the United Nations treaties of friendship with other countries and the conventions of the International Labor Organization.

The United Nations Charter, which was ratified in 1945, has two general sections that lay the framework for broad treaty provisions in the field of health.

Article 55 provides in part: "The United Nations shall promote solutions of international, economic, social, health and related problems."

Article 56 provides that "all members of the United Nations pledge themselves to take joint and separate action in cooperation with the organization for the achievement of the purposes set forth in Article 55."

Agreements and treaties negotiated pursuant to these provisions could fundamentally change medical practice in this country if ratified by two-thirds of the Senate present and voting.

The second example deals with a series of friendship treaties that were before the Senate this past year. These include treaties with Denmark, Holland, Israel, and Greece, which dealt with immigration quotas, citizenship requirements, and matters of professional licensure in the various states. If these treaties had been ratified as originally prepared, some of the requirements of the state medical licensing boards would have been abrogated.

The International Labor Organization, an affiliate of the United Nations, in June, 1952, adopted a convention known as the "Minimum Standards of Social Security." This convention includes almost all of the socialist medical proposals that have until now been rejected by the Congress. If this convention is ratified under the existing provision of our Constitution, government control of medicine will have been achieved. Because of the danger of the socialization of medicine via international treaty, the American Medical Association favors a redefinition of existing treaty-making powers.

The exact wording of a suitable amendment is a matter for constitutional lawyers to determine, not for physicians. The House of Delegates of the American Medical Association recognized the impropriety of an action to endorse the wording of any specific bill and therefore endorse the principles embodied in Senate Resolution No. 1. Whether modifications of that resolution achieve the objectives sought is primarily a legal issue. Certainly the interest of the medical profession in this historic and constitutional controversy is wholly proper. The action of the House of Delegates was based on careful study, the resolution adopted temperate and reasonable.

NATIONAL ENGINEERS' WEEK

National Engineers' Week is being observed February 21-27. The engineering profession, important to the American way of life, is aiding in the maintenance of America's supremacy in the adaptation of newly discovered, barely explored forces of nature to the needs of the day. Scientific discoveries provide the foundation for engineering development. It is the engineering application of these discoveries to the development and production of great quantities of equipment that characterizes America's power.

The achievements of engineers in the development of processes and equipment that have promoted and contributed to health are considerable and far reaching. One example is the development of the modern, sensitive electrocardiograph from the original Einthoven galvanometer produced in 1893. Another is the development of Roentgen's discovery of x-rays into modern diagnostic and therapeutic uses. Still another example of engineering and medicine working together is the application of the newly developed transistor to the hearing aid. An even more recent, and continually growing application of this cooperation is in the field of atomic medicine, in which radioactive isotopes are produced from an atomic pile for use in medicine. By working together in the future as they have in the past, the potential of medicine and engineering is unlimited.

EPIDEMIC NAUSEA, VOMITING, AND DIARRHEA

Little is known concerning so-called epidemic nausea, vomiting, and diarrhea. The general opinion appears to favor a viral etiology, chiefly because no known specific primary enteric pathogens have been recovered from the patients affected. Reimann and associates¹ administered to experimental subjects fresh, filtered broth garglings and suspensions of diarrheal stools from patients sick with epidemic diarrhea, nausea, and vomiting. The nebulized filtrates were inhaled in a closed container. Within a few days, in many of the experimental subjects malaise, headache, abdominal discomfort, nausea, vomiting, and diarrhea developed. Some had a nasopharyngitis. The investigators concluded that the noxious agent was a filtrable virus that was air borne and entered the body through the respiratory tract. It was present in the oropharynx and intestinal tract.

Felsen² postulated the gastrointestinal manifestations to be focal and nonspecific. The primary viral agent is extra-enteric and probably located in the respiratory tract. It is, therefore, a systemic disease with focal intestinal manifestations. The viral agent is generally of a low order of virulence and appears to confer no lasting immunity. In limited studies thus far no striking intestinal lesions have been noted by sigmoidoscopy. The disease appears to be readily transmissible, possibly as much by the respiratory route as by fecal material. It is likely to be seen in epidemic form in association with, or chrono-

logically about the time of so-called influenza outbreaks. There may also be some epidemiological relationship to viral hepatitis A, the inciting agent of which is eliminated in the stools, and the virus of poliomyelitis, which is also found in the feces. There may even be a carrier state in epidemic nausea, vomiting, and diarrhea, and cases appear sporadically between major outbreaks. Most of the cases encountered by Felsen have been self-limited, mild, and of short duration. Strict isolation precautions are indicated in all cases.

THE COST OF MEDICAL PERIODICALS

Relatively few physicians in the United States subscribe to more than five medical journals, mostly those written in English. A serious problem, however, confronts the many medical libraries that have a limited budget but must keep a fairly complete file not only of journals published in the United States but of foreign ones as well. The cost of some of these is excessively high and is in some cases prohibitive. For this reason the periodicals and serials committee of the Medical Library Association has made a series of comparative studies of the cost to medical libraries in this country of medical periodicals from various parts of the world. The first such survey was made in 1926, and in the 1930's there were some substantial reductions in price.

The survey for 1948-1950-1952 has been completed and analyzed for various countries on the basis of average cost per page to the subscriber. The South American journals showed the lowest cost—0.76 cent, as compared with 0.93 cent for the United States. All other countries showed a higher average cost, but, excluding one group of German publications, which averaged 4.46 cents, only four journals (one Belgian, one British, one Italian, and one Swiss) exceeded 3 cents a page. Reflecting the general inflation the costs in most countries have risen during the period of the survey, an average of 15.5% in the United States as compared with comparable figures for 1946. The average annual subscription cost of 75 leading medical journals in the United States was \$6.60 each, as compared with an average of \$40.30 each for 30 German periodicals from one prominent publisher and of \$12.55 each for 15 German publications from other publishers.

The unfortunate result of these high prices for German journals is that the work of many excellent German scientists does not receive the wide audience it deserves. As for our libraries, if the present trend continues, they will be forced more and more to depend on the large lending libraries and to forego their individual subscriptions to the higher priced journals.

ORGANIZATION SECTION

A. M. A. HAWAIIAN TOUR

Many physicians and their wives who plan to attend the American Medical Association's annual convention in San Francisco, June 21-25, also plan to take part in the A. M. A. 13-day Hawaiian Holiday Tour, leaving San Francisco by air on the night of Friday, June 25, and returning on the S. S. Lurline, sailing on July 3, and arriving in Los Angeles on July 8. All reservations are being handled by William M. Moloney, General Agent, Room 711, 105 West Adams Street, Chicago (3). Since the Hawaii Medical Association is planning both a scientific and a social program for the visiting physicians and their wives, we have asked Dr. A. S. Hartwell, who has been a delegate from Hawaii to the American Medical Association, to write his impressions of the coming tour. Herewith, he describes what the party from the mainland can expect when it visits Honolulu.—ED.

About 90 years ago Mark Twain, then working in Honolulu as a reporter for the *Sacramento Bee*, described Hawaii as "the loveliest fleet of islands that lies anchored in any ocean."

profusion of exotic tropical plants and flowers. The A. M. A. party will be staying at Waikiki beach, best known of the Hawaiian playgrounds. Waikiki, the beach area of Honolulu, is on Oahu. This is the "entrance" island of the five resort islands, where vacationers arrive from the mainland of the United States. From Oahu visitors fly to Kauai, Maui, Molokai, and Hawaii islands, each of which offers distinctive scenery.

All five of the islands have complete facilities for visitors. Kauai is noted for its greenery and lush tropic vistas. Maui, historic "Valley Isle," has mighty Haleakala, dormant crater large enough to swallow Manhattan. Molokai is a retreat with cliffs of waterfalls and villages where old customs are followed. Hawaii, biggest of the group, has deserts and jungles, active volcanoes, and acres of orchids. Pineapples are a year-around sight on all of the major islands, and canning is a year-around industry, but June to September is the time of the most abundant fruit and the most activity.

When the A. M. A. party drives from the Honolulu airport or Pearl Harbor to the Royal Hawaiian hotel, the doctors and their wives will pass cannery districts tangy with the scent of

The Hawaii Medical Association is planning a *Luau*, or feast, like the one shown above, for the American Medical Association's party to the islands. Guests wear bright Hawaiian apparel, sit on mats spread on the ground, and partake of such Polynesian dishes as pig roasted underground, coconut pudding, fresh pineapple, and poi and watch continuous hula and song entertainment.

Since that time great progress in industry and agriculture has done little to change that definition. Broad highways, beach and hillside homes, and rolling acres of sugar cane and pineapple have not interfered with the natural beauty of Hawaii.

Members of the Hawaii Medical Association are looking forward to the visit by doctors and their wives from the mainland after the A. M. A. meeting in San Francisco. The association, under the chairmanship of Dr. Walter B. Quisenberry of the Department of Health of the Islands, has arranged a panel-type program for June 28 and 29. A big social affair has also been planned. This will be held on Tuesday evening, June 29, at the Niimalu hotel. You will find in Hawaii a truly hospitable people and a welcome that could far exceed anything you have experienced in the past.

The Hawaii Visitors Bureau, as a representative of the people of Hawaii, will be on hand to provide a gala and warm welcome and to assist you while you are here in planning any visits to the other islands in the Hawaiian chain. June, like other months of the year, has a most delightful climate, with a minimum amount of trade wind showers and the complete

simmering pineapple juice. On tours around the island, the visitors will drive for miles through plantations where workers race to get the fragrant pines picked while flavor is at its height. In the world's largest fruit-packing plant in Honolulu they will see dozens of machines shelling 100 pineapples a minute and rows of women and girls trimming the fruit as fast as it is spilled onto their work tables. There is no charge for tours of the plants.

What impresses many visitors is the fact that there are no billboards on the highways and hills. A group of scenic-minded women, the Outdoor Circle, have tabooed the beauty-blighting signs. The party may also see some of the spectacular ceremonial dances of the island Japanese. In cities and villages whole families of kimono-wearing islanders gather in lantern-lit clearings for community Bon dances. Originally purely religious in meaning, the ceremonies descend from the dance of joy of an early Buddhist disciple whose mother was saved from purgatory. Vacationers, drawn to the dance grounds by the drums and wailing oriental flutes, find the dances good camera material.

Water sports, as the teen-agers would say, are "the most." Waikiki is surf-riding headquarters. There is no short cut to expert and trick riding, but often, after only a day's lesson, visitors are able to navigate lying down, and a few surprise themselves by riding a roller standing up.

Needless to say, the food is excellent. From miso soup to lichee nuts, Hawaii has a lot to offer in the food department. Doctors with a taste for the unusual try Samoan baked bread-fruit, Korean jijin mandoo, Japanese namasu, Portuguese sausage, Chinese sin choy, and Hawaiian kalua pig. The latter will be served at one of the parties being planned. Fresh fruit addicts can try papayas, pineapples, mangos, apple-sweet bananas, guavas, and two-pound avocados. Vegetarians will find vegetables they have never heard of. Of course, there are plenty of American dishes. Everywhere in the islands pure food laws and health inspectors safeguard the visitors. A. M. A. gourmets may eat their way along the resort chain with nothing to fear except a growing waist line.

IOWA STATE MEDICAL SOCIETY

The Iowa State Medical and Chirurgical Society, later renamed the Iowa State Medical Society, came into being in 1850 as a direct outgrowth of the third annual session of the American Medical Association in Boston the preceding year. Inspired by the appeal that he heard there, on his return to Iowa Dr. John F. Sanford of Farmington wrote to many physicians urging the organization of a state medical society and later traveled by stage and steamer to several cities to enlist cooperation. As a result, 25 "pioneer practitioners of medicine" met at Burlington, June 19, 1850, and adopted a constitution "for the purpose of harmonizing the profession of medicine, and to promote its usefulness and respectability." The group resolved that "to promote the best interests of the profession, of community and mankind, and also to cultivate the social and scientific relations of its members, together with all the benefits flowing from concert of action, mutual interchange of opinion, and a better understanding of each other's character, and in order to render more effective the great objects of the State Society, we would recommend to our brethren in each county, the formation of a medical society, in each, auxiliary to the State Society." Among the charter members whose interest Dr. Sanford enlisted was Dr. J. C. Hughes of Keokuk, who was affiliated for many years with the College of Physicians and Surgeons of Keokuk, serving as dean of the faculty at the time of his death.

At the second meeting of the society in Fairfield in 1851, Dr. Sanford, reporting on "the causes which contribute to depress the sciences and dignity of the medical profession of Iowa," inveighed against (1) "the practice of admitting young men to the study of medicine without a respectable preliminary education"; (2) the influence of ignorance among members of the profession, which, he stressed, "stands pre-eminent for public virtue, probity and usefulness, yet the individual shortcomings of its members have often excited a popular and erroneous prejudice against it"; and (3) "the practice of attending families by the year," pointing out that "The medical services of an enlightened and benevolent physician are not to be made an article of traffic and bargain. His commerce is with health, the lives and happiness of the human race, and should be as free from purely mercenary influences as his honor and reputation."

During the Civil War years 1862 and 1863, the society did not convene, but in 1864 a reorganization session was held in Iowa City. In 1867 the attendance at the annual session had grown so large (35 old and new members) that it was decided

to hold a two day meeting. The following year the meeting in Des Moines was referred to in the presidential address as an epoch in its history, the meeting being "the first ever held in the state capitol, and to be regarded as an indication of the realization of our long cherished hopes that the influence of our society is being extended, and that it shall be felt over the entire state, and at each succeeding annual meeting, all parts of the state shall be fully represented." Articles of incorporation were signed at this meeting.

In 1903 at Sioux City the Iowa State Medical Society adopted a new constitution and bylaws, placing it in conformity with the reorganization plan of the American Medical Association, which proposed that "every regular and reputable physician in the United States become a member of his county society, by thus doing, becoming a member of his state society and finally becoming a member of the American Medical Association." The next year at the annual session in Des Moines it was reported that 87 of the 99 county societies had been organized under the new plan; that in 55 counties where societies were not in existence, such organizations had been formed; and that the total membership had reached about 1,500, or a gain in one year of about 100%. Within a few years all county societies (95 single and 2 double county bodies) were organized under it.

According to Dr. Walter L. Biering, in "One Hundred Years of Iowa Medicine," "the establishment of medical schools

in Iowa corresponds with the society organization of the profession." The College of Physicians and Surgeons of Keokuk, in 1847 was moved to Madison, Wis., where it became the Medical Department of the University of Wisconsin. The school then migrated to Rock Island in 1848, to become the College of Physicians and Surgeons of the Upper Mississippi; in 1849 it moved to Davenport and in 1850 came to Keokuk, where it remained for 58 years and where it was referred to

as the Medical Department of the Iowa State University, a designation which it retained until 1870, when the medical school established at Iowa City claimed the title. The first session of the Drake University Medical School opened in Des Moines in October, 1882, and that of the Sioux City Medical College was held in 1887. Through discontinuance and merger, the Keokuk Medical Schools, Sioux City Medical College, and Drake University Medical School have been centered since 1913 in one institution, the College of Medicine of the University of Iowa at Iowa City.

The society, which began in 1850 with 25 members, now has 100 times that number. In 1952, when it moved into its new headquarters, 97% of all eligible physicians in the state were members. Among its current projects are (1) a physician relations department, (2) a weekly television program over WOITV, the educational station at Iowa State College, (3) a manual of health resources available in Iowa, (4) a manual on industrial health for small plants that do not have in-plant physicians, and (5) a series of physician-pharmacist meetings. The society publishes the *Journal of the Iowa State Medical Society*, the first number of which appeared July 1, 1911. Officers of the society included Dr. Ben T. Whitaker, Boone, president; Dr. Robert N. Larimer, Sioux City, president-elect; and Dr. Allan B. Phillips, Des Moines, secretary.

STUDENT A. M. A. NOW HAS 65 CHAPTERS

Chapter strength in the Student American Medical Association reached 65 recently when the students at Georgetown University School of Medicine, Washington, D. C., voted to affiliate. Several other schools are in the process of establishing chapters before SAMA's 4th convention, May 1-3, in Chi-

cago, but at the moment the following medical schools are without representation: Stanford, Howard, George Washington, Johns Hopkins, Harvard, Columbia, Rochester, New York Medical, Cornell, South Carolina, Tennessee, Vanderbilt, Vermont, St. Louis, Washington, and Dartmouth.

FEDERAL MEDICAL LEGISLATION

Philippine Veterans' Service-Connected Disabilities

Senator Johnson (D., Colo.) proposes in S. 2712 to extend the terminal date of service in the Philippine Insurrection from July 15, 1903, to Jan. 1, 1914. Veterans of such service would be eligible to file Philippine veterans' service-connected claims for medical and hospital care. This bill was referred to the Committee on Labor and Public Welfare.

Senators Gillette (D., Iowa), Martin (R., Pa.), and Neely (D., W. Va.), have introduced S. 2681, which provides "that veterans of the Spanish-American War, including the Boxer Rebellion and the Philippine Insurrection, who are in need of out-patient treatment, shall, upon application for such out-patient treatment by the Veterans' Administration, be deemed, for the purposes of such out-patient treatment, or for emergency hospital care incident to such treatment, to have incurred their disease or disabilities as a direct result of military or naval service, in line of duty, during such war." The bill was referred to the Committee on Labor and Public Welfare.

Congressman Elliott (D., Ala.) has introduced H. R. 7112, which would provide domiciliary medical and hospital treatment by the Veterans Administration for veterans of the Spanish-American War, including the Boxer Rebellion and Philippine Insurrection. This bill was referred to the Committee on Veterans' Affairs.

Social Security Extension

Congressman Reed (R., N. Y.), in H. R. 7199, introduced the administration's bill for extended social security coverage, effective Jan. 1, 1955, to an additional 10 million persons. For 6½ million of these coverage would be on a compulsory basis, including self-employed physicians. This bill is a later version of the administration's bill, H. R. 6812, introduced during the preceding session of the 83rd Congress and reported previously. In addition to covering additional categories, the bill would: (1) raise benefits and increase from \$3,600 to \$4,200 the individual income limit on which the 2% social security tax would apply—a \$12 annual per capita increase—with the ultimate tax being 3½% instead of 3¼%, the employer and the employee each contributing ultimately 3½% by 1970 for this retirement plan, and the self-employed having a proportioned increase in their ultimate tax rate; (2) eliminate the lowest four years of the worker's earnings in computing benefits, whereas under H. R. 6812 the lowest years would be dropped; (3) increase the payments for a minimum of \$25 to \$30 monthly and a maximum family benefit from \$168.75 to \$190; (4) permit retiring persons under 75 to earn \$1,000 a year instead of \$75 a month; and (5) protect the benefit rights if one becomes blind or totally disabled for an extended period by excluding the period of disability in computing the average earnings. The disabilities would have to extend beyond six months and be medically determined. To qualify, the employee must have been covered for at least half of the time in the preceding 10 years. The Secretary of the Department of Health, Education, and Welfare, would contract with the state vocational and rehabilitation agencies to determine disability. State agencies would arrange to obtain the necessary medical information. If they were dissatisfied with the determination, they would have a right to a hearing and judicial review. Disabled persons would be referred to the state rehabilitation agency for indicating rehabilitation services. The bill was referred to the Ways and Means Committee.

College Education for the Disabled

Congressman Elliott (D., Ala.), in H. R. 7113, would provide federal aid to states to set up college level education plans for the physically handicapped persons between 16 and

45. The state plan would have to establish a "schedule of maximum fees for medical and surgical treatment, hospitalization and prosthetic devices." This bill was referred to the Committee on Education and Labor.

Hospital Surveys and Construction

Congressman Wolverton (R., N. J.) has introduced H. R. 7341, the administration's bill to enlarge the scope of the Federal Hospital Survey and Construction Act (Hill-Burton) to include the construction of public and nonprofit diagnostic treatment centers, chronic disease centers, rehabilitation centers, and nursing homes. It authorizes an appropriation of 2 million dollars for state survey need of facilities and 60 million dollars for construction yearly for a three year period. States would be allowed a minimum of \$25,000 for building surveys but would have to match the federal money equally. The public or nonprofit agencies sponsoring the construction project would have to match the federal donation. Grants would be based on the state's population and per capita income as under the present hospital construction act with a minimum allotment per state of \$100,000 for diagnostic treatment and chronic disease hospitals and \$50,000 for nursing homes and rehabilitation centers.

State agencies would recommend and approve all construction, and the act would be administered by the U. S. Public Health Service. The 60 million dollars annually for construction over a three year period, for 1955-1957 would be divided as follows: 20 million dollars for nonprofit diagnostic or treatment centers, 20 million dollars for nonprofit disease hospitals, and 10 million dollars each for nonprofit rehabilitation facilities and nursing homes. This bill was referred to the Interstate and Foreign Commerce Committee.

STATE MEDICAL LEGISLATION

Arizona

Bills Introduced.—H. 86, proposes the enactment of a hospital lien law creating a lien in favor of hospitals for hospital charges for the care and treatment of injuries of persons admitted to the hospitals under certain circumstances. H. 91, proposes the creation of an Arizona commission on alcoholism to, among other things, initiate, develop, and administer a program for the study, treatment, and rehabilitation of resident alcoholics. H. 138 and S. 42, propose to authorize any person who may otherwise validly make a will to, by will or otherwise, dispose of the whole or any part of his or her body to a teaching institution, university, college, state department of health, facility designated or maintained by the anatomy board of Arizona, legally licensed hospital or any other agency or commission operating a tissue, eye, bone, cartilage, or blood bank or any other bank of a similar kind designated for the purposes of medical science and the rehabilitation of the maimed. H. 142, to amend the law relating to chiropractic, proposes among other things that licentiates of the chiropractic board may not practice physical therapy or naturopathy. The proposal also requires applicants for license to be citizens of the United States.

Kentucky

Bills Introduced.—H. 48, proposes to authorize the board of trustees of the University of Kentucky to employ a qualified person who shall formulate all necessary plans for the establishment of a medical school at the university. H. 91 and S. 63, propose the creation of a Kentucky commission on alcoholism to study the problems of alcoholism within the state, to formulate and carry out programs of education designed to curb the excessive use of alcohol and reduce the number of inebriates, to establish such facilities and employ such personnel as are necessary and available for the diagnosis and rehabilitation of inebriates, to accept for examination, diagnosis, guidance, and treatment any persons coming to it of its own volition for advice and guidance. H. 149, proposes the enactment of a bill designed to provide effective control of the spread of communicable tuberculosis. H. 151, proposes the enactment of a bill to provide for the effective control of the spread of rabies.

Maryland

Bill Introduced.—H. 3, proposes amendments to the medical practice act which in effect eliminate the references in the present Act to the Maryland State Homeopathic Medical Society and abolishing the Homeopathic Examining Board.

Massachusetts

Bills Introduced.—H. 948, proposes an act to prohibit the attendance in schools of children suffering from tuberculosis in a communicable form and providing for periodic examination of school children. H. 1540, proposes the creation of a special commission to make an investigation and study relative to the desirability and feasibility of the acquisition by the commonwealth of certain hospitals, property of the federal government,

which have been closed. H. 1639, proposes the creation and establishment of a psychiatric nursing school under the management and control of the trustees of the University of Massachusetts. H. 2279, proposes the creation of a special unpaid commission to make a study and investigation relative to the establishment of a state medical and dental school under the jurisdiction of the University of Massachusetts. H. 1997, proposes to make it unlawful for any hospital doing business in the State to charge more than 25 cents per page for a hospital record. H. 2102, proposes to authorize the department of education and the department of mental health to make a study and investigation relative to the advisability of establishing compulsory mental health programs in the public schools. S. 612, proposes the creation of a special commission to make an investigation relative to the sale, furnishing, delivery, exchange, and use of narcotic drugs within the commonwealth.

Bills Enacted.—H. 48, has become Chapter 44 of the Laws of 1954. It provides that a physical examination and treatment by a registered physician or surgeon acting under the authority of the department of public health upon the person of a minor who voluntarily appears therefor shall not constitute an assault or an assault and battery upon such minor.

Michigan

Bills Introduced.—H. 23, proposes to create an office of health affairs which shall consist of a bureau of hospital survey and construction, a bureau of alcoholism, and such other bureaus or divisions as may be deemed desirable or necessary. H. 164, to amend the workmen's compensation act, proposes to require employers to furnish necessary dental care to injured employees. H. 184, proposes the enactment of a hospital licensing act. H. 205, to amend the medical practice act relating to the granting of temporary licenses, authorizes the granting of such licenses under certain conditions to doctors of medicine who have entered the United States under any act of Congress and are residents of the state prior to Jan. 1, 1952. S. 1082, to amend the basic science act provisions relating to the circumstances under which the board may waive the examination, proposes that such examinations may be waived when the applicant is of good moral character and possesses a high school education or its equivalent, when he has passed in one other state or territory a written examination in the basic sciences given by the official basic science board of the other state and the examination and passing requirements, at the time of passage, were substantially equal to those required by the basic science board of Michigan, and upon compliance with certain other provisions. S. 1097, proposes that no person who, while a patient at any state hospital, receives psychiatric shock treatment, and as a result thereof suffers physical or mental injury or death, shall thereafter have a cause of action for damages against any officer, employee, physician, or technician of such hospital unless injury or death shall have resulted from the gross and wanton negligence of such officer, employee, physician, or technician giving or supervising the giving of such shock treatment.

New York

Bills Introduced.—A.R. 8, proposes the creation of a joint legislative committee to make a comprehensive study of existing law dealing with the illicit use of drugs and to make recommendations for remedial legislation relating thereto. A. 4 and S. 11, propose the enactment of a community mental health services act. A. 182, proposes to require applicants for an operator's or chauffeur's license to prove that they are in good mental and physical health and free from any heart or cardiovascular disease and any mental defect or disorder, such proof to be based upon a certificate of a duly licensed physician. A. 189, to amend the education law, proposes to require boards of education to provide adequate health services for pupils attending schools who are 15 years of age and over and whose parents consent thereto. A. 290, to amend the vehicle and traffic law, proposes to require applicants for an operator's or chauffeur's license to pass such eye tests as will satisfy the commissioner that he is competent to operate a motor vehicle. A. 326, to amend the penal code, proposes that a person who shall falsely make, alter, forge, or counterfeit a doctor's prescription shall be guilty of forgery. A. 345 and S. 281, to amend the tax law, propose that a taxpayer who is a duly licensed physician and who is on the staff of, and actually performs services as often as twice monthly at, a free clinic, dispensary or outpatient unit operated by or affiliated with a hospital maintained in whole or part by a municipality of this state, shall be granted an additional personal exemption of \$2,500. A. 452, proposes the creation of a state board of examiners for x-ray technicians and defines an x-ray technician as one who performs professional service requiring the application of principles of x-ray, such as responsible supervision of a patient requiring skillful application of technical procedures and the accurate recording of facts, and carrying out of procedures as prescribed by a licensed physician or dentist. A. 457, A. 1572 and S. 351, propose to prohibit any person from obtaining or attempting to obtain a barbiturate drug or preparation by means of fraud, deceit, misrepresentation, concealment, or the like. A. 731 and S. 772, to amend the insurance law, propose that no membership corporation or consumers' cooperative stock corporation which publicly offers a prepayment medical care plan, shall limit its subscribers' right to be cared for by any duly licensed physician or dentist or partnership of physicians or dentists. A. 733, to amend the education law relating to disciplinary proceedings against practitioners of medicine, proposes that a vote of eight members of the committee, rather than a unanimous vote, shall be sufficient to find a practitioner guilty of charges. A. 740, to amend the workmen's compensation law, proposes that if an employer or insurance carrier fails to submit an arbitration agreement to the physician or hospital which renders services to the injured employee, the physician or hospital may force their claims for services in an action at law. A. 742, A. 796 and S. 631, to amend the education law relating

to the practice of physiotherapy, provide for the granting of certain temporary licenses to physiotherapists which shall be good for a period of six months for persons practicing physiotherapy in a hospital or in a public health agency. A. 801 and S. 1002, to amend the education law relating to conditional admission for medical licensing examination, add bacteriology to the list of subjects which shall be covered by the examination of applicants 19 years of age who have completed two years of medical study. A. 813, to amend the mental health law, authorizes the department of mental hygiene to conduct mental health research programs including projects involving research, investigations, experiments, and demonstrations relating to the cause, diagnosis, treatment, cure, and prevention or control of mental illness and mental deficiency. A. 814, proposes the creation of a temporary state commission to make an investigation and study of the problem of the care and protection of patients in mental hospitals and of the use of jackets and other mechanical restraints in the treatment of such patients and of the techniques and practices presently employed for such purpose. A. 902 and S. 695, to amend the social welfare law relating to the definition of a dispensary, propose to except therefrom the department of hospitals of the city of New York and any hospital or institution operated by such department. A. 1118 and S. 751, to amend the vehicle and traffic law, propose that applicants for a chauffeur's or operator's license shall be required to pass eye tests satisfactory to the commissioner or file a certificate from a duly licensed physician or optometrist attesting that the applicant has been examined as to his eyesight and found competent to operate a motor vehicle. A. 1189 and S. 910, propose the creation of a temporary state commission to undertake and complete a thorough study of the feasibility of requiring each resident of the state to take an annual health examination. A. 1230, to amend the insurance law, proposes that non-profit medical and dental indemnity and hospital service corporations shall furnish medical and dental care by duly licensed physicians and dentists of the subscriber's choice whether such persons are designated or approved by the corporation or not. A. 1231 and S. 1254, to amend the insurance law, propose that in any case in which the state or a political subdivision of the state contributes part or all of the cost of medical or dental expense indemnity or hospital service, the subscriber shall have the right to select for such expense indemnity or service any non-profit medical care plan authorized and approved by the department of insurance. A. 1235, to amend the medical practice act relating to the revocation of licenses for granting rebates or splitting fees, proposes that such provision shall not apply where the physician has participated in rendering of medical and/or surgical care, in which event such participation shall be certified to by the physician and the fee therefor be commensurate with the services rendered, and further, that the patient to whom such medical and/or surgical care shall have been rendered shall be advised of the participation and of the distribution of the fee therefor. A. 1381, to amend the insurance law relating to medical expense indemnity corporations, proposes to authorize such corporations to furnish podiatric care through duly licensed podiatrists. S.R. 32, proposes the creation of a committee to make a comprehensive investigation of the policies, acts, methods, practices, services, and charges of persons, firms, associations and corporations owning, operating, conducting, and maintaining hospitals, clinics and sanitariums and to investigate all complaints of the people against hospitals, clinics, and sanitariums. S. 383, to amend the vehicle and traffic law, proposes to require applicants for operator's and chauffeur's licenses to pass such eye tests as will indicate that he is competent to operate a motor vehicle, or shall present a certificate from a duly licensed physician or optometrist that the applicant has been examined as to his eyesight and found competent to operate a motor vehicle. S. 514, proposes the creation of a consumer's bureau in the state department of health for the purpose of protecting the consumer in the manufacture and sale of adulterated or misrepresented foods, drugs, cosmetics, or health devices. S. 611, proposes to authorize hospitals supported in whole or part by public funds to employ physicians and surgeons under a contract or salary arrangement for the medical diagnosis and/or the treatment of patients only when such diagnosis and treatment is a public charge. In all other cases such medical diagnosis and/or treatment shall be rendered to patients in the hospital independently of other hospital charges and under contractual relationship between the patient and the physician or physicians. S. 914, proposes to make it unlawful for the trustees, officers and managers of any nonsectarian hospital, sanitarium, or other institution to refuse to employ a physician, surgeon, intern, or nurse or to refuse to allow any physician, surgeon, intern, or nurse to gain admission to and use the facilities of the hospital solely because of the race, creed, color, or religion of such physician, surgeon, intern, or nurse. S. 1069, to amend the public health law, proposes to add regulations relating to the care, treatment, guidance, and rehabilitation of narcotic drug users. S. 1291, proposes that every municipal corporation shall assume the liability of resident physicians and interns, as well as physicians, who render medical services to persons without receiving compensation from such person, in public institutions maintained in whole or in part by the municipal corporation, for damages for personal injuries alleged to have been sustained by such person. S. 1302, proposes to make it unlawful for any person to possess or maintain a vending machine from which are sold or offered for sale drugs, medicines, or appliances intended or having special utility for the prevention of venereal diseases. S. 1479, proposes the creation of a temporary state commission to make a comprehensive study and survey of the state laws relating to the licensure of professional practices and including laws relating to optometry, dentistry, pharmacy, nursing, podiatry, osteopathy, and physiotherapy and to consider the necessity or desirability of revising the present laws to require the licensing of other practices related to human health and physical or mental well-being.

MEDICAL NEWS

CALIFORNIA

Radiological Conference.—The sixth annual midwinter Radiological Conference, sponsored by the Los Angeles Radiological Society, will be held at the Ambassador Hotel, Los Angeles, Feb. 20-21. Out-of-state speakers will include Drs. Eugene P. Pendergrass, Philadelphia, Ursus V. Portmann, Tucson, Ariz., Marcy L. Sussman, Phoenix, Ariz., and Frederic E. Templeton, Seattle. A banquet preceded by cocktails will be held at the Ambassador Hotel, Feb. 20. Conference reservations may be made through Dr. Harold P. Tompkins, 658 S. Westlake Ave., Los Angeles 57. The conference fee is \$20, and the dinner will be \$7.50 per plate. Courtesy cards for the conference are available to radiological residents and radiologists in military service by preregistration.

Postgraduate Convention at Los Angeles.—The Alumni Postgraduate Convention of the College of Medical Evangelists, Los Angeles, will meet at the Biltmore Hotel, Los Angeles, Feb. 23-25. The meeting will be preceded by two days of refresher courses at the White Memorial Hospital on the Los Angeles campus. Daily panel discussions at 11 a. m. will be preceded by lectures as follows: Tuesday, "Management of Hip Fractures in the Aged" by Dr. Harold B. Boyd, Memphis, Tenn., 1953 president of the American Academy of Orthopedic Surgeons; "Present Status of Antibiotics in the Armed Forces" by Major Gen. George E. Armstrong, Washington, D. C., Surgeon General, U. S. Army; and "Appraisal of Use of Modern Antibiotics in Urology" by Dr. Louis M. Orr, Orlando, Fla., will precede the panel "A Second Look at the Miracle Drugs." Wednesday, "Proctologic Problems Which Should be Managed in the Hospital" by Dr. Louis A. Buie, Rochester, Minn.; "Diagnosis and Management of Carcinoma of the Female Generative Organs" by Dr. Walter J. Reich, Chicago; and "Radiation Treatment of Cancer of the Larynx" by Dr. Hugh F. Hare, Los Angeles, will precede a panel on problems in cancer management. Thursday a panel on postoperative medical complications will be preceded by the following presentations: "Present Status of Dietary vs. Endogenous Cholesterol in Pathogenesis of Atheromatous Disease" by Dr. William Dock, Brooklyn, and "Effects of Malposition in Anesthesia" by Col. Harvey C. Slocum. Round-table luncheons led by the convention speakers will be held Tuesday and Thursday. Other speakers and their first presentations include: Dr. Lester R. Dragstedt, Chicago, "New Light on Physiology of Gastric Secretion and Its Relation to Peptic Ulcer," Dr. Harrison S. Evans, Worthington, Ohio, "Practical Measures for the Management of Psychiatric Problems in General Practice," and Dr. Denis J. Browne, London, England, "Early Diagnosis and Treatment of Orthopedic Conditions in Children." Preregistration forms and reservations for the banquet, Wednesday, should be requested from the Managing Director, Alumni Postgraduate Convention, 316 N. Bailey St., Los Angeles 33.

DISTRICT OF COLUMBIA

Psychiatric Jurisprudence.—The Washington School of Psychiatry is presenting eight lectures on psychiatric jurisprudence by Dr. Winfred Overholser, superintendent of Saint Elizabeths Hospital. These lectures, which began Feb. 1 and are held on Mondays, 8-10 p. m., cover the following topics: (1) requisites of sound mental examination; (2) wills and deeds, torts, credibility of witnesses; (3) divorce and annulment, commitment laws; (4) criminal litigation; (5) establishment of responsibility; (6) opinion evidence; (7) doctors in court; and (8) existing interrelations and possible methods of improvement. Information may be obtained from the Washington School of Psychiatry, 1711 Rhode Island Ave., N. W., Washington 6, D. C., telephone STerling 3-4373.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

GEORGIA

Society News.—At the regular meeting of the South Georgia Medical Society the following officers were elected: Dr. Robert E. Perry Jr., Valdosta, president; Dr. Jesse L. Parrott, Hohira, vice-president; and Dr. Joseph H. Brannen, Valdosta, secretary-treasurer.

Graduate Medical Assembly.—The Atlanta Graduate Medical Assembly will be held at the Biltmore Hotel, Feb. 22-24. The following symposiums will be presented (3:30-5 p. m.): Monday, "Isotopes, in Diagnosis and Therapy"; Tuesday, "Cardiology" and "Obstetrics and Gynecology" (the latter at the Academy of Medicine); Wednesday, "Gastroenterology." Guest speakers and their first presentations include:

Oscar T. Clagett, Rochester, Minn., Surgical Treatment of Tumors of the Mediastinum.

Virgil S. Counseller, Rochester, Minn., Clinical and Surgical Problems Encountered in Vesicovaginal Fistula.

Elmer Belt, Los Angeles, The Urgent Need for Early Recognition of Cancer of the Prostate.

Charles A. Doan, Columbus, Ohio, The Lymphomata—Differential Recognition and Management.

Allan C. Barnes, Columbus, Ohio, Experimental Nonsurgical Therapy of the Pelvic Malignancy.

Julius W. McCall, Cleveland, Diseases of the Larynx and Management.

Dorothy H. Andersen, New York, Celiac Disease and Starch Intolerance.

R. Gordon Douglas, New York, Late Bleeding in Pregnancy.

Robert L. Sanders, Memphis, Tenn., Surgery of the Upper G. I. Tract.

Philip J. Hodes, Philadelphia, Roentgen Manifestations of Pancreatic-ampullary Carcinoma.

Dr. Harold P. McDonald, Atlanta, is chairman of the session, and Dr. Evert A. Bancker, Atlanta, has been appointed chairman of the 1955 meeting.

ILLINOIS

Society News.—The Illinois chapter of the American College of Chest Physicians held a joint meeting with the Chicago Roentgen Society at the Sheraton Hotel, Chicago, Feb. 11. Dr. Leo G. Rigler, professor of radiology, University of Minnesota Medical School, Minneapolis, discussed "The Roentgenologic Aspects of Diseases of the Pulmonary Vessels."

Clinics for Crippled Children.—The University of Illinois Division of Services for Crippled Children has scheduled the following clinics, which will be held in cooperation with local medical and health organizations:

Feb. 23, Effingham (rheumatic fever), Douglas Township Building; Peoria, St. Francis Hospital.

Feb. 24, Elgin, Sherman Hospital; Springfield (cerebral palsy), Memorial Hospital.

Feb. 25, Anna, City Hospital; Bloomington, St. Joseph's Hospital.

Feb. 26, Chicago Heights (rheumatic fever), St. James Hospital.

Physicians may refer or bring to a convenient clinic any child for whom examination or consultative services are desired.

Chicago

Seminars on Alcoholism.—Portal House of the Chicago Committee on Alcoholism is presenting a series of seminars on alcoholism in the Chicago Community Fund Conference Rooms, 123 W. Madison St., 7:30-9:30 p. m. on Tuesdays. "Problems of Understanding the Alcoholic" was presented Feb. 16; "Helping the Alcoholic" will be presented Feb. 23; "Community Action of Alcoholism" March 2; and "The Alcoholic and the Courts," March 9.

Society News.—At the meeting of the Chicago Society of Physical Medicine and Rehabilitation, Feb. 24, 8 p. m., at Stritch School of Medicine of Loyola University, 706 S. Wolcott St., Dr. Paul A. Nelson of the Cleveland Clinic will discuss "Foundation of Ultrasonics in Medicine" and Dr. Otto F. Hug, instructor in pathology at the Max Planck Institute for Biophysics of Frankfurt-on-the-Main, Germany, will discuss "Effects of Ultrasound on Tissues."

Program on Cardiac Surgery.—Dr. Walter S. Priest, chairman, scientific section, Chicago Heart Association, will preside at a meeting Feb. 23, 8 p. m., in the Chicago Academy of Sciences, 2001 N. Clark St., when the following program on long-term results of cardiac surgery will be presented, with Dr. James A. Campbell as moderator:

Postoperative Observations on Patients with Tetralogy of Fallot, Willis J. Potts and Edward J. Berman.

Postoperative Observations on Patients with Isolated Pulmonary Stenosis, Stanley Gibson.

Coarctation of the Aorta, William E. Adams.

Mitral Stenosis. Influence of Preoperative Selection, Ormand C. Julian.

IOWA

Program on Surgical Types of Heart Disease.—A program on surgical types of heart disease will be presented Feb. 20-21 at the Art Center, Grand Ave. at Polk Blvd., Des Moines, under the auspices of the department of internal medicine at Iowa Methodist Hospital, Des Moines. Physicians are cordially invited. A clinic will be held at the Art Center Sunday morning. The Saturday program includes:

David G. Pugh, Rochester, Minn., Use of X-Ray and Fluoroscopy in Diagnosis of Heart Disease.

O. Henry Janton, Philadelphia, Selection of Patients for Mitral Valve Surgery.

Francis F. Rosenbaum, Milwaukee, Use of Electrocardiograms in the Diagnosis of Surgical Heart Disease.

S. Gilbert Blount Jr., Denver, Diagnosis of Congenital Heart Disease from the Clinical Point of View.

KANSAS

Hearing and Speech Conference.—A short hearing and speech conference will be held at the University of Kansas Medical Center, Kansas City, Feb. 26-27, to bring together persons working in this field or vitally interested in some of the problems. The program is open to school administrators, physicians, psychologists, public health nurses, speech therapists, occupational and physical therapists, teachers, and others interested in the education of children with hearing and speech handicaps.

KENTUCKY

Today's Health.—On request of the Woman's Auxiliary, the council of the Kentucky State Medical Association has agreed that a subscription to *Today's Health* be presented to each of the 93 bookmobiles that will travel throughout the state, lending reading material to Kentuckians who do not have adequate library facilities.

Auxiliary's Christmas Gift.—A new station wagon was presented as a Christmas gift to the Kentucky chapter of the American Cancer Society by the Woman's Auxiliary to the Kentucky State Medical Association in a special ceremony, Dec. 17, 1953, in front of the KSMA headquarters office, Louisville. Money for the new station wagon, the second that the Kentucky physicians' wives have given to the cancer group, was contributed by the 24 local auxiliary chapters throughout the state.

MARYLAND

Conference on Vitamin B₁₂.—"The Clinical Aspects of Vitamin B₁₂" will be presented at 9 a. m., Feb. 20, at the Johns Hopkins University School of Hygiene and Public Health, 615 N. Wolfe St., Baltimore. Drs. Norman H. Jolliffe, New York, Daniel F. Downing, Philadelphia, and Margaret Merrell, Sc.D., Baltimore, will serve as discussants for "Vitamin B₁₂ and the Growth of Children" (chairman, Bacon F. Chow, Ph.D., Baltimore). "The Absorption of Vitamin B₁₂" will be discussed by Drs. William B. Castle, Boston, Frank H. Bethell, Ann Arbor, Mich., Julius R. Krevans, Baltimore, Robert F. Schilling, Madison, Wis., and others, with C. Lockard Conley, Baltimore, as chairman for this topic and for "Other Clinical Uses of B₁₂" which will be discussed by Dr. Bernard Becker, Baltimore, and others. A summary of highlights of the conference will be given by Dr. Robert S. Goodhart, New York. Attendance at these informal conferences will be by invitation only.

MASSACHUSETTS

House Officers' Lecture.—The House Officers' Association of New England Center Hospital, Boston, announces that on Feb. 23 at 7 p. m. Dr. Alexander B. Gutman, professor of medicine, Columbia University College of Physicians and Surgeons, New York, will discuss "Primary and Secondary Gout" in the Stearns Auditorium of New England Center Hospital. All interested persons are invited.

Medicolegal Pitfalls.—Judge Frank J. Donahue, Massachusetts Superior Court, will serve as moderator for the session on legal pitfalls in medical practice that will be presented by the Norfolk District of the Massachusetts Medical Society in the Boston Medical Library (Ware Hall), 8 The Fenway, Feb. 23, 8:15 p. m. Judge Donahue will discuss malpractice; Mr. Eugene H. Giroux, chairman, Massachusetts Division of Industrial Accidents, how the physician should conduct himself before the industrial accident board; and attorney John M. Russell, "Testimony of the Attending Physician and the Expert."

MICHIGAN

Lecture on Poisonous Plants.—Charles R. Dawson, Ph.D., of Columbia University will open the spring lecture series on "Frontiers in Chemistry" at Wayne University, Detroit, with a discussion of "The Toxic Principle of Poison Ivy and Related Plants" at 7:15 p. m., Feb. 22.

Bloodmobile Service Discontinued.—The state department of health announces that its bloodmobile service will be discontinued Feb. 26 and that fresh blood will thereafter be collected entirely by local blood banks and the American National Red Cross regional blood centers. Sources of blood for the manufacture of blood derivatives by the department's laboratories are now considered sufficient to supply the needs of Michigan's people without the bloodmobile service. The change was made possible because of the development of processes in the laboratories for recovering gamma globulin and albumin from human placentas. The department, which now has working agreements with 22 hospitals to supply it with about 50,000 placentas a year, plans to enlarge this program. Other products will be made from surplus and outdated blood furnished the laboratories by 61 blood banks. Dr. Albert E. Heustis, Lansing, health commissioner, points out that after March 1 the Michigan Department of Health will not be able to provide emergency supplies of whole blood as it has in the past and urges donors to step up their support of their local blood banks so that an adequate supply of whole blood may be available to them at all times.

MISSOURI

Annual Loeb Lecture.—The Alpha Pi chapter of the Phi Delta Epsilon medical fraternity will sponsor the annual Hanau W. Loeb lecture at the St. Louis University School of Medicine Feb. 25, 5 p. m. Dr. Albert B. Sabin, professor of research pediatrics, Children's Hospital Research Foundation, Cincinnati, will present "Experimental Production of Avirulent Variants of Poliomyelitis Virus." Dr. Sabin is the author of numerous papers on pneumococcus infection, infantile paralysis, virus diseases, and other topics relating to infectious diseases.

NEW JERSEY

Chest Physicians Meet in Jersey City.—The New Jersey chapter of the American College of Chest Physicians, at its meeting, Feb. 23, 8:30 p. m., at Berthold S. Pollak Hospital for Chest Diseases, 100 Clifton Place, Jersey City, will discuss "Pulmonary Emphysema and Cor Pulmonale." Etiology, pathogenesis, physiology, diagnosis, and medical management will be presented by Drs. Rejane M. Harvey, associate in medicine, and M. Irene Ferrer, assistant professor of clinical medicine, Columbia University College of Physicians and Surgeons, New York, and surgical considerations by Dr. Ross J. Simpson, assistant attending thoracic surgeon, Berthold S. Pollak Hospital for Chest Diseases.

Course in Forensic Medicine.—The Passaic County Medical Society is sponsoring six monthly lectures covering workmen's compensation disputes, negligence actions, criminal matters, and other topics pertinent to forensic medicine. The course, which is held on Wednesday evenings, 8 p. m., at the medical society building, 625 Broadway, Paterson, began with "The Heart in Industry" by Dr. Cary Eggleston, New York, and will include:

Feb. 24, Ruptured Intervertebral Disks, David M. Bosworth, New York.
 March 24, The Arthritides, Roy R. Schubert, Paterson.
 April 28, Occupational Skin Diseases, Louis Tulipan, New York.
 May 19, The Neuropsychiatric Laborer, speaker to be announced.
 June 23, Pitfalls in Expert Testimony, Mr. Arthur Mead.

The fee for the course is \$5.

Meeting on Maternal Fatalities.—The Obstetrics and Gynecology Section of the Academy of Medicine of New Jersey will meet with the Advisory Committee on Maternal Welfare of the Medical Society of New Jersey at the office of the society, 315 W. State St., Trenton, Feb. 25, 8:30 p. m. Dr. John D. Preece will serve as moderator for "Presentation of Maternal Fatalities" by Drs. Samuel A. Cosgrove, Jersey City, Robert A. MacKenzie, Asbury Park, and Philip F. Williams, Philadelphia. This meeting will follow a meeting of the Field Physicians and State Society Advisory Committee on Maternal Welfare at 3 p. m. Physicians interested in attending an informal "Dutch treat" dinner between these two meetings are requested to communicate with Dr. Preece at the office of the Medical Society of New Jersey.

NEW YORK

Hospital News.—The 16th in the series of Dr. Henry Joachim lectures on the application of fundamental sciences in medicine will be delivered by Dr. Abraham White, associate dean, Albert Einstein College of Medicine of Yeshiva University, who will present "Aspects of Pituitary-Adrenal Cortical Physiology," Feb. 22, 8:30 p. m. in the Auditorium, Freeman Pavilion, Jewish Sanitarium and Hospital for Chronic Diseases, 86 E. 49th St., Brooklyn. At the same time and place on Feb. 25, Dr. Saul B. Gusberg, assistant professor of gynecology, Columbia University College of Physicians and Surgeons, New York, will speak on the developmental concept of cervical cancer.

Circuit Riding Teams for Child Guidance Centers.—A new child guidance clinic center, recently opened by the State Department of Mental Hygiene in Rochester, is the 12th such center maintained by the department, each staffed by a traveling clinic team. A total of 59 New York State communities receive regularly scheduled service from these centers. Provision has been made in state appropriations for the addition of two more clinic teams, which are to be appointed as soon as the professional personnel can be obtained. Children, referred by school personnel, courts, social agencies, or by parents, are studied and treated for habit disorders, conduct disturbances, neurotic behavior, and personality difficulties, as well as for early symptoms of psychosis. Dr. Donald W. Cohen, chief child guidance psychiatrist, directs the department's clinical program. Serving in rotation with psychiatric social workers and a clinical psychologist on the new traveling team operating from the Rochester center are Drs. Donald J. McIntosh and Oscar K. Diamond of the Willard State Hospital staff, who will conduct the clinic every Monday at Canandaigua. On Tuesdays Dr. James M. Murphy and Dr. Harold A. O'Connor, both of Willard, will hold a clinic at Seneca Falls. A clinic will be conducted at Albion every Wednesday by Dr. Guy M. Walters of Rochester State Hospital. On Thursdays Drs. Edward D. Stevenson, Wassaic, and Harry Feldman, New York City, will hold a clinic at Lyons.

New York City

Rehabilitation Case Conference.—An unrehearsed rehabilitation case conference will be presented by the staff of the Institute for the Crippled and Disabled at the meeting of the New York chapter, National Rehabilitation Association, Feb. 25, 7 p. m., 23rd St. at First Ave., New York.

Meetings on Cancer.—On Feb. 24, 5 p. m., the New York Academy of Medicine will present "Cancer Detection" by Drs. Cornelius P. Rhoads, Henry T. Randall, Emerson Day, George N. Papanicolaou, and Genevieve M. Bader. At the same time, March 3, Dr. Hayes Martin will discuss "Head and Neck Cancer."

The Goldforb Lecture.—This lectureship, sponsored for the second year by students and colleagues of Abraham J. Goldforb, Ph.D., will be held Feb. 25 at 8:30 p. m. in the New York Academy of Medicine Building, 5th Ave. at 103rd St. Vincent du Vigneaud, Ph.D., professor of biochemistry, Cornell University Medical School, will speak on the chemical nature and biological activity of the hormones of the posterior pituitary. Members of the scientific professions are invited.

Golden Jubilee of Clinical Society.—On Feb. 20 at the Waldorf-Astoria Hotel, the Clinical Society of the New York Polyclinic Medical School and Hospital will celebrate its 50th anniversary. Dr. Orrin Sage Wightman, one of the founders of the society, will be guest of honor. Dr. Wightman, who was formerly professor of internal medicine of the New York Polyclinic Medical School and Hospital and a member of its board of trustees, is a past president of the New York County and New York state medical societies and is presently chairman of the board of trustees of the New York Academy of Medicine.

OHIO

Aaron Brown Lecture.—Chi chapter of Phi Delta Epsilon fraternity, Ohio State University College of Medicine, Columbus, will sponsor the annual Aaron Brown lecture, Feb. 23, 8 p. m., at the Ohio State University Health Center. Dr. Walter L. Palmer, University of Chicago School of Medicine, will discuss "Recent Advances in the Interpretation of Gastric Analysis." An early afternoon gastroenterology seminar or clinic will also be presented.

OKLAHOMA

Society News.—At the meeting of the Tulsa County Medical Society, Feb. 22, 8 p. m. at The Mayo, Dr. W. James Gardner of Cleveland will discuss "Relief of Trigeminal Neuralgia by Decompression of the Sensory Root."

WASHINGTON

Medical Aspects of Civil Disaster.—A symposium on the medical aspects of civil disaster is scheduled at University of Washington, Seattle, Feb. 20. Dr. R. L. Larsen, Seattle, civil defense coordinator, will serve as moderator for the following program, which will be presented at 9:35 a. m. after a briefing on the present status of civil defense in Seattle, King County, and Washington:

- Shock—Its Prevention, Early Recognition and Treatment, David Metheny, Seattle.
- Use of Blood, Plasma and Plasma Expanders. Blood Grouping, Matching and Transfusion in Mass Treatment, Quinn B. DeMarsh, Seattle.
- Detection of Radiation—Early Diagnosis and Treatment of Radiation Illness, Simeon T. Cantril, Seattle.
- Mass Treatment of Thermal Burns, Henry N. Harkins, Seattle.
- Treatment of Infant and Child Casualties, Frederic C. Moll, Seattle.
- Approach to Treatment of Severe Multiple Injuries, Edward B. Speir, Seattle.
- Psychiatric Aspects of Disaster; Prevention and Treatment of Panic, William Y. Baker, Seattle.
- Evaluation of Chemical Warfare Agents and Treatment of Casualties, Frank J. Leibly, Seattle.
- Biological and Bacteriological Warfare, Alfred Lazarus, Ph.D., Seattle.

WEST VIRGINIA

Dr. Ogden Honored.—Dr. Chester R. Ogden's 50 years of service to Clarksburg were celebrated Nov. 6, 1953, when the Lions Club surprised him with a luncheon on the eve of his 80th birthday. Dr. Ogden has served as president of the Harrison County and West Virginia State Medical associations and from 1912 to 1920 was a member of the A. M. A. House of Delegates.

CANAL ZONE

50 Year Jubilee in Panama.—The Inter-American Medical Convention, which will be held at the El Panama Hotel, Panama City, Panama, March 24-26, under the sponsorship of the Medical Association of the Isthmian Canal Zone, will commemorate both the 50th year of Panamanian independence and the 50th year of the advent of American medicine in the Canal Zone with the appearance of General William C. Gorgas in 1904. The meeting, which will be attended by physicians from North, Central, and South America, will be opened at 9 a. m. Wednesday by His Excellency, Col. Jose Antonio Remon Cantera, president, Republic of Panama, after which Dr. Irving J. Strumpf, Balboa, president, Medical Association of the Isthmian Canal Zone, will deliver the address of welcome. Col. Joseph R. Shaeffer of the U. S. Army will present "Current Status of Plasma Expanders"; Dr. Bernardino Gonzalez-Ruiz, chief surgeon, Hospital Santo Tomas, "Experiences in the Use of Largactil—A New Anesthetic Agent"; and Dr. Oswald S. Lowsley, New York, will speak. From 12 noon to 1 p. m. President Remon will receive visitors at the Presidencia. The following program will be presented from 2 to 4 p. m.:

Francis P. McCarthy, Boston, Diseases of the Oral Cavity.

Robison D. Harley, Philadelphia, Topical Diagnosis of Third and Sixth Cranial Nerve Lesions.

Samuel Thompson, New York, Technique for Use of Magnesium Silicate in Surgical Therapy of Coronary Artery Disease.

Thursday will be devoted to a panel on tropical medicine, with Dr. Edward I. Salisbury, United Fruit Company, as moderator in the morning and Dr. Benjamin H. Kean, New York, as moderator for the afternoon session, participating with Drs. Herbert C. Clark, director, Gorgas Memorial Laboratory of Tropical Medicine; Dr. Mark T. Hoekenga, chief of medical service, La Lima Hospital, Honduras; Dr. Carl Johnson, pathologist, Board of Health Laboratory and Health Officer, Panama; and Dr. Harold W. Brown, dean, School of Public Health, Columbia University, New York. Friday morning Dr. LeRoy Goodman, assistant professor of obstetrics, gynecology, and oncology, University of Kansas Medical Center, Kansas City, will discuss "Newer Concepts in the Causes of Bleeding in the Female," and presentations will be made by Drs. Isidor S. Ravdin, University of Pennsylvania School of Medicine, Philadelphia, and Mortimer N. Hyams, New York University-Bellevue Hospital Medical Center. An elaborate program of tours and entertainment for physicians and their wives has been planned. There is no charge for registration or attendance at the convention. Information may be obtained from the secretary, Medical Association of the Isthmian Canal Zone, Box "A," Balboa Heights, Canal Zone.

GENERAL

Physical Medicine Archives on Microfilm.—A microfilm edition of the *Archives of Physical Medicine and Rehabilitation* has been made available to libraries. The microfilm edition will be distributed at the end of the volume year. Information may be obtained from University Microfilms, 313 N. First St., Ann Arbor, Mich.

New England Diabetes Association.—A meeting of the New England Diabetes Association will be held at Hanover, N. H., Feb. 26-27. Dr. Israel M. Rabinowitch, Montreal, Canada, will speak Friday evening, 8 p. m. A clinical conference at the Veterans Administration Center, White River Junction, Vt., Saturday, 9:30 a. m., is open to interested persons.

Surgeons Meet in Reno.—The American College of Surgeons extends an invitation to all physicians to attend its sectional meeting at the Riverside Hotel, Reno, Nev., Feb. 25-26. A symposium on trauma will be presented Thursday morning and panel discussions on intestinal obstruction and the prevention and treatment of postoperative pulmonary complications Thursday afternoon. Thursday, 8:30-10 p. m., there will be a symposium on cancer. A panel discussion on jaundice will be held during luncheon Friday, 12 noon to 1:30 p. m., a symposium on atomic injuries, 2-3:25 p. m., and a panel discussion on complications of peptic ulcer, 3:35-5 p. m.

Sioux Valley Medical Society.—The Sioux Valley Medical Society will hold its annual meeting Feb. 23-25 in Sioux City, Iowa. Tuesday at 8 p. m. Dr. Amos C. Michael, Vermillion, S. D., will discuss "Dehydration, with Emphasis on Possible Complications of Low Salt Diets." The Woodbury County Medical Society will be hosts at the smoker and Dutch lunch that will follow. A sound motion picture, "Oxygen Dosage and Techniques," will open the Wednesday morning meeting, and one on the exfoliative cytological method in the diagnosis of gastric cancer will precede the Thursday morning session. Guest speakers will include:

Egbert H. Fell, Chicago, Cardiac Arrest.

Charles K. Kirby, Philadelphia, Neoplasms of the Lower Esophagus and Stomach.

John P. Wendland, Minneapolis, Diagnostic and Prognostic Significance of Retinal Findings in Hypertension.

Louis A. Brunsting, Rochester, Minn., Systemic Lupus Erythematosus.

Leon S. McGoogan, Omaha, Endometriosis.

The presidential address at the informal banquet Wednesday, 7 p. m., will be followed by "European Travelogue (1953)" by Dr. Omar A. Stauch, Sioux City, Iowa. Ladies are expected.

Fellowship in Honor of Russell Wilder.—The National Vitamin Foundation invites holders of doctorate degrees in medicine or one of the biological sciences, interested in continuing training in the science of nutrition, to become candidates for the fellowship recently established in honor of Russell M. Wilder of the emeritus staff of the Mayo Clinic. The three year fellowship, effective Sept. 1, pays the recipient \$4,500 the first year, \$5,000 the second, and \$5,500 the third year. Application forms, obtainable from the offices of the National Vitamin Foundation at 15 E. 58th St., New York 22, must be returned to the foundation on or before March 15, accompanied by a letter from the executive officer of the institution at which the work is to be done and by a letter from the head of the department under which the candidate is to work, attesting that the candidate will be permitted and encouraged to carry on his work and studies in the institution and department indicated. The candidate must (1) outline a program of investigation that must be approved by his preceptor and (2) give reasonable assurance that he will complete his fellowship and continue to work in the field of nutrition after the period covered by the fellowship. Applicants will be notified of action taken on or before July 1.

Tri-State Meeting.—The 55th annual meeting of the Tri-State Medical Association will be held Feb. 22-23 at the Francis Marion Hotel, Charleston, S. C. At 10 a. m. Dr. J. Jennings Cleckley, Charleston, will serve as moderator for a symposium on neuropsychiatry, which will include "The Treatment of Hypochondriasis," "Sub-Insulin Shock in Mild Nervous Conditions," and "Use of Ancillary Psychiatric Personnel and Community Resources in Treatment." At 11:15 a. m. a panel on trauma will be moderated by Dr. John A. Siegling, Charleston, in which "Injuries to the Cervical Spine" and "Fractures of the Humerus" will be discussed. The morning session will end with a presentation on atomic medicine by Rear Adm. Charles F. Behrens (MC), U.S.N. After luncheon, clinical demonstrations will be presented by the faculty of the Medical College of South Carolina. A social hour will precede the banquet, 8 p. m., at which Dr. G. Grady Dixon, Ayden, N. C., will deliver the presidential address. On Tuesday, 10:30 a. m., a pediatric panel will be presented. At 8 p. m. the association will have a combined meeting with the Charleston County Medical Society in Baruch Auditorium, where Dr. Gordon D. Hoople, medical director, Hearing and Speech Center, Syracuse (N. Y.) University, will discuss "Help for the Hearing Handicapped."

Meeting on Forensic Sciences.—The American Academy of Forensic Sciences will hold its annual meeting at the Drake Hotel, Chicago, Feb. 25-27 under the presidency of Dr. Louis J. Regan, Los Angeles. The first general scientific session, Thursday morning, will include a talk by Col. Calvin H. Goddard (MC), U. S. Army, Washington, D. C., entitled "Police

Science: Europe's Contribution to America"; "Suicide and Insanity—As Seen by the Pathologist" by Dr. Philipp R. Rezek, Miami, Fla.; "Sudden Deaths in Infants" by Dr. George J. Carroll, Suffolk, Va.; "Establishing a Medical Examiner's System in a Small Rural State" by Dr. Joseph W. Spelman, Burlington, Vt.; and a discussion of cardiac lesions in cases of sudden death by Dr. Stanley H. Durlacher and Arthur Fisk, B.S., New Orleans, and Drs. William V. Lovitt Jr. and Russell S. Fisher, Baltimore. The following presentations will be given at the afternoon session:

Observations on Some New Blood Factors, Alexander S. Wiener, Brooklyn.

Inherent Hazards of Blood Transfusion, Lester J. Unger, New York.

Application of Blood Grouping in Disputed Paternity, Sidney B. Schatkin, LL.B., New York.

Application of Blood Grouping in the Examination of Blood Stains—Legal Aspects, Briggs J. White, Ph.D., Washington, D. C.

Heredity of Factors S and Kell, Fred H. Allen, Boston.

The Blood Factor f, Alan R. Jones, Boston.

Hemolytic Transfusion Reactions—Medicolegal Aspects, John Elliott, Ph.D., Miami, Fla.

Blood Grouping in Disputed Paternity, Leon N. Sussman, New York.

Dr. Arnold F. Strauss, Norfolk, Va., will serve as moderator for a medicolegal slide seminar Friday, 9 a. m. A seminar on blood group nomenclature will also be held Friday morning. Participants will include Drs. Lester J. Unger and Leon N. Sussman, New York, and Fred H. Allen and Alan R. Jones, Boston. Friday afternoon Dr. Jacob Werne, Edgewood, Md., and Dr. Irene Garrow, Long Island City, N. Y., will speak on legal pitfalls in the performance of medicolegal autopsies. At the annual banquet Friday, 7 p. m., Stanley N. Barnes, assistant attorney general, Department of Justice, Washington, D. C., will discuss "The Judge Looks at the Forensic Scientist." The final session, Saturday morning, will include the following presentations:

Traumatic Rupture of the Aorta with Dissecting Aneurysm, Frederick P. Bornstein, El Paso, Texas.

Two Unusual Cases of Fatal Poisoning: A. Systemic Fluoride Poisoning Following Skin Burns by Hydrofluoric Acid; B. Acetic Acid Poisoning with Hemoglobinuric Nephrosis, Frederick D. Newbarr, Los Angeles.

Results of a Blood Alcohol Testing Program in a Rural State, Joseph W. Spelman, Burlington, Vt.

Statistical Analysis of Toxicologic Cases, Niels C. Klendshoj, Buffalo.

PHILIPPINE ISLANDS

Commemorative Postage Stamp.—The post office in Manila recently placed on sale a new postage stamp commemorating the 50th anniversary of the founding of the Philippine Medical Association, Sept.

15, 1903. The association, starting with a few members, mostly American physicians, has grown to a total membership of 3,300 practicing physicians. The stamp, as seen in the illustration, has for its motif a boy lying on an examination table in a clinic, a physician at his side. The stamp bears the seal of the Philippine Medical Association and the legend "50th Anniversary 1903-1953."

FOREIGN

Scandinavian Congress on Anesthesiology.—The Scandinavian Society of Anesthesiologists extends a cordial invitation to members of the American Society of Anesthesiologists to attend and participate in the third Congress of the Scandinavian Society of Anesthesiologists in Copenhagen, June 11-12. The theme of the program, artificial respiration, will cover (1) physiology, methods, and apparatus and (2) respiratory treatment in clinical practice. Entry of papers must reach the secretary-general, Dr. Henning Poulsen, The Surgical University Departments, Aarhus, Denmark, not later than March 1,

and entry of participation in the congress is to be sent to the secretary, Dr. Valdemar Foght-Nielsen, Central-Hospital, Slagelse, Denmark, before April 15.

CORRECTIONS

Internship and Residency Number.—The statistics published in the Internship and Residency Number of THE JOURNAL, Sept. 26, 1953, are erroneous in table 8, page 280. Through a mechanical error, in the I. B. M. tabulating procedure 700 additional residency appointments were assigned to Psychiatry. The number of residencies filled Sept. 1, 1952, in this field was 833 rather than 1,533 as listed.

The Federal Income Tax.—In THE JOURNAL, Feb. 6, in the article "The Physician's Federal Income Tax," on page 522, under the heading *Equipment*, the word average should have been "salvage" in the third sentence in the last paragraph.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

ANNUAL CONGRESS ON INDUSTRIAL HEALTH, Brown Hotel, Louisville, Ky., Feb. 24-25. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago 10, Secretary.

NATIONAL CONFERENCE ON RURAL HEALTH, Baker Hotel, Dallas, Texas, Mar. 4-6. Mrs. Arline Hibbard, 535 N. Dearborn St., Chicago 10, Secretary.

AERO MEDICAL ASSOCIATION, Hotel Statler, Washington, D. C., March 29-31. Dr. Thomas H. Sutherland, P. O. Box 26, Marion, Ohio, Secretary.

ALABAMA, MEDICAL ASSOCIATION OF THE STATE OF, Mobile, April 15-17. Dr. Douglas L. Cannon, 537 Dexter Ave., Montgomery, Secretary.

AMERICAN ACADEMY OF FORENSIC SCIENCES, Drake Hotel, Chicago, Feb. 25-27. Prof. Ralph F. Turner, Michigan State College Dept. of Police Administration, East Lansing, Mich., Secretary.

AMERICAN ACADEMY OF GENERAL PRACTICE, Cleveland, March 22-25. Mr. Mac F. Cahal, 406 West 34th St., Kansas City 2, Mo., Executive Secretary.

AMERICAN ASSOCIATION OF ANATOMISTS, Hotel Galvez, Galveston, Texas, April 7-9. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

AMERICAN ASSOCIATION OF IMMUNOLOGISTS, Ambassador Hotel, Atlantic City, N. J., April 11-15. Dr. John Y. Sugg, 1300 York Ave., New York, Secretary.

AMERICAN ASSOCIATION OF PATHOLOGISTS AND BACTERIOLOGISTS, Houston, Texas, April 8-10. Dr. Alan R. Moritz, 2085 Adelbert Road, Cleveland 6, Secretary.

AMERICAN ASSOCIATION OF RAILWAY SURGEONS, Drake Hotel, Chicago, April 6-8. Dr. Chester C. Guy, 5800 Stony Island Ave., Chicago 37, Secretary.

AMERICAN COLLEGE OF ALLERGISTS, Roney Plaza Hotel, Miami Beach, Fla., April 5-10. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

AMERICAN DERMATOLOGICAL ASSOCIATION, The Greenbrier, White Sulphur Springs, W. Va., April 13-17. Dr. J. Lamar Callaway, Duke Hospital, Durham, N. C., Secretary.

AMERICAN HEART ASSOCIATION, Conrad Hilton Hotel, Chicago, April 1-4. Dr. William H. Bunn, 44 East 23d St., New York 10, Secretary.

AMERICAN ORTHOPSYCHIATRIC ASSOCIATION, Hotel Commodore, New York, March 11-13. Dr. Marion F. Langer, Room 210, 303 Lexington Ave., New York 16, Executive Secretary.

AMERICAN PHYSIOLOGICAL SOCIETY, Ambassador Hotel, Atlantic City, N. J., April 10-16. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Executive Secretary.

AMERICAN PSYCHOSOMATIC SOCIETY, Jung Hotel, New Orleans, March 27-28. Dr. Theodore Lidz, 333 Cedar St., New Haven 11, Conn., Secretary.

AMERICAN RADIUM SOCIETY, The Homestead, Hot Springs, Va., March 14-16. Dr. Robert E. Fricke, 102 Second Ave. S.W., Rochester, Minn., Secretary.

AMERICAN SOCIETY OF BIOLOGICAL CHEMISTS, Atlantic City, N. J., April 12-16. Dr. Philip Handler, Duke University, Durham, N. C., Secretary.

AMERICAN SOCIETY FOR EXPERIMENTAL PATHOLOGY, Atlantic City, N. J., April 12-16. Dr. Cyrus C. Erickson, 874 Union Ave., Memphis 3, Tenn., Secretary.

AMERICAN SOCIETY FOR PHARMACOLOGY AND EXPERIMENTAL THERAPEUTICS, Atlantic City, N. J., April 12-16. Dr. Carl C. Pfeiffer, 1853 West Polk St., Chicago 12, Secretary.

CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE, Palmer House, Chicago, March 2-5. Dr. Maurice M. Hoeltgen, 86 East Randolph St., Chicago, Secretary.

DALLAS SOUTHERN CLINICAL SOCIETY, Dallas, March 15-18. Dr. T. Haynes Harvill, 433 Medical Arts Bldg., Dallas 1, Texas, Secretary.

EASTERN SECTION, AMERICAN CONGRESS OF PHYSICAL MEDICINE, Newark, N. J., April 10. Dr. H. L. Rudolph, 400 North Fifth St., Reading, Pa., Secretary.

EASTERN SURGICAL SOCIETY, Boston, March 26-27. Dr. J. William Hinton, 130 East 79th St., New York, Secretary.

FEDERATION OF AMERICAN SOCIETIES FOR EXPERIMENTAL BIOLOGY, Convention Hall, Atlantic City, N. J., April 12-16. Dr. M. O. Lee, 2101 Constitution Ave., Washington 25, D. C., Secretary.

ISTHMIAN CANAL ZONE, MEDICAL ASSOCIATION OF THE, El Panama Hotel, Panama City, R. P., March 24-26. Dr. I. Robert Berger, Box "A," Balboa Heights, Canal Zone.

JOHN A. ANDREW CLINICAL SOCIETY, Memorial Hospital, Tuskegee Institute, Ala., April 11-16. Dr. Eugene H. Dibble Jr., John A. Andrew Memorial Hospital, Tuskegee Institute, Ala., Secretary.

MICHIGAN CLINICAL INSTITUTE, Sheraton-Cadillac Hotel, Detroit, March 10-12. Dr. L. Fernald Foster, 606 Townsend St., Lansing 15, Mich., Secretary.

MISSOURI STATE MEDICAL ASSOCIATION, Hotel Jefferson, St. Louis, April 4-7. Dr. E. Royce Bohrer, 634 North Grand Blvd., St. Louis 3, Secretary.

NATIONAL CONFERENCE ON CARE OF THE LONG-TERM PATIENT, Edgewater Beach Hotel, Chicago, March 18-20. Dr. Dean W. Roberts, 615 N Wolfe St., Baltimore 5, Director.

NATIONAL CONFERENCE ON TRICHINOSIS, A. M. A. Headquarters, Chicago, March 1. Dr. S. E. Gould, Wayne County General Hospital, Eloise, Mich., Chairman.

NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS, Jefferson Hotel, St. Louis, March 10-12. Dr. F. M. Foote, 1790 Broadway, New York 19, Executive Director.

OHIO STATE MEDICAL ASSOCIATION, Columbus, April 13-15. Mr. Charles S. Nelson, 79 East State St., Columbus 15, Executive Secretary.

PACIFIC NORTHWEST SOCIETY OF PLASTIC AND RECONSTRUCTIVE SURGEONS, Seattle, April 3. Dr. E. E. Banfield, Medical Arts Bldg., Tacoma 2, Wash., Secretary.

REGIONAL MEETINGS, AMERICAN COLLEGE OF PHYSICIANS:

TOPEKA, KANS., March 19. Dr. William C. Menninger, 3617 West 6th Ave., Topeka, Kansas, Governor.

RICHMOND, VA., Feb. 25. Dr. Charles M. Caravati, 807 West Franklin St., Richmond 20, Va., Governor.

SECTIONAL MEETINGS, AMERICAN COLLEGE OF SURGEONS:

FRENCH LICK SPRINGS, Indiana, French Lick Springs Hotel, March 15-17. Dr. Carl H. McCaskey, 20 N. Meridian St., Indianapolis 4, Chairman.

MONTREAL, CANADA, Mount Royal Hotel, March 31-April 2. Dr. Harry S. Morton, 900 Sherbrooke St., West, Montreal, Canada, Chairman.

OMAHA, NEB., Hotel Fontenelle, March 1-4. Dr. Earl A. Connolly, 107 South 17th St., Omaha, Chairman.

RENO, NEV., Riverside Hotel, Feb. 25-26. Dr. Kenneth F. Maclean, 120 N. Virginia St., Reno, Nev., Chairman.

SOUTHEASTERN ALLERGY ASSOCIATION, Dinkler-Plaza Hotel, Atlanta, Ga., March 25-27. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 1, S. C., Secretary.

SOUTHEASTERN SURGICAL CONGRESS, Tutwiler Hotel, Birmingham, Ala., March 8-11. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta, Ga., Secretary.

WESTERN SOCIETY OF ELECTRO-ENCEPHALOGRAPHY, Del Monte Lodge, Pebble Beach, Calif., March 7-8. Dr. Sylvester N. Berens, 902 Boren Ave., Seattle, Secretary.

FOREIGN AND INTERNATIONAL

ASSOCIATION OF SURGEONS OF GREAT BRITAIN AND IRELAND, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

BRITISH MEDICAL ASSOCIATION, Glasgow, Scotland, July 1-9, 1954. Dr. A. Macrae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

CANADIAN MEDICAL ASSOCIATION, Vancouver, B. C., Canada, June 14-18, 1954. Dr. T. C. Routley, 244 St. George St., Toronto 5, Ontario, Canada, General Secretary.

CONFERENCE OF INTERNATIONAL UNION AGAINST TUBERCULOSIS, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Fisiología, Ciudad Universitaria, Madrid, Spain.

CONGRESS OF INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF BLINDNESS, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

CONGRESS OF INTERNATIONAL ASSOCIATION FOR THE STUDY OF THE BRONCHI, Geneva, Switzerland, June 5-6, 1954. Professor A. Montandon, Clinique Universitaire d O.R.L., Hôpital Cantonal, Geneva, Switzerland, Chairman.

EUROPEAN SOCIETY OF CARDIOVASCULAR SURGERY, Edinburgh, Scotland, July 9-10, 1954. For information address: Mr. A. J. Slessor, Department of Surgery, University New Building, Edinburgh 8, Scotland.

HEALTH CONGRESS OF THE ROYAL SANITARY INSTITUTE, Scarborough, England, April 27-30, 1954. Mr. P. Arthur Wells, Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1, England, Secretary.

INTERNATIONAL ANESTHESIA RESEARCH SOCIETY, Los Angeles, Calif., U. S. A., Oct. 10-14, 1954. For information write: Dr. T. H. Seldon, 102-110 Second Avenue S.W., Rochester, Minn., U. S. A.

INTERNATIONAL CANCER CONGRESS, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

INTERNATIONAL CONFERENCE ON THROMBOSIS AND EMBOLISM, Basle, Switzerland, July 20-24, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

INTERNATIONAL CONGRESS OF CLINICAL PATHOLOGY, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A. Moore, Washington University School of Medicine, St. Louis 10, Mo., U. S. A., Chairman, Committee on Arrangements.

INTERNATIONAL CONGRESS ON DISEASES OF THE CHEST, Barcelona, Spain, Oct. 4-8, 1954. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Ill., U. S. A., Executive Secretary.

INTERNATIONAL CONGRESS ON GROUP PSYCHOTHERAPY, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

INTERNATIONAL CONGRESS ON GYNECOLOGY AND OBSTETRICS, Geneva, Switzerland, July 26-31, 1954. Dr. H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

INTERNATIONAL CONGRESS OF HEMATOLOGY, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6^e, France, Secretary.

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE, Rome and Salerno, Italy, Sept. 13-20, 1954. For information write: Segreteria XIV Congresso Internazionale di Storia della Medicina, Istituto di Storia della Medicina, Citta Universitaria, Rome, Italy.

INTERNATIONAL CONGRESS OF HYDROCLIMATISM AND THALASSOTHERAPY, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni venac 1, Belgrade, Yugoslavia, Secretary General.

INTERNATIONAL CONGRESS OF INDUSTRIAL MEDICINE, Naples, Italy, Sept. 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Policlinico, Naples, Italy, Chairman, Organizing Committee.

INTERNATIONAL CONGRESS OF INTERNAL MEDICINE, Stockholm, Sweden, Sept. 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, Sweden, Secretary-General.

INTERNATIONAL CONGRESS OF INTERNATIONAL COLLEGE OF SURGEONS, São Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Ill., U. S. A., Secretary-General.

INTERNATIONAL CONGRESS ON MENTAL HEALTH, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY, Buenos Aires, Argentina, April 21-28, 1954. Direccion General de Sanidad Militar, Pozos 2045, Buenos Aires, Argentina.

INTERNATIONAL CONGRESS OF NUTRITION, Amsterdam, Netherlands, Sept. 14-18, 1954. For information write: Dr. M. van Eekelen, Centraal Instituut voor Voedingsonderzoek T.N.O., 61 Catharynesingel, Utrecht, Netherlands.

INTERNATIONAL CONGRESS OF OPHTHALMOLOGY, University of Montreal and McGill University, Montreal, Canada, Sept. 9-11, 1954, and Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 12-17, 1954. Dr. William L. Benedict, 100 First Avenue Building, Rochester, Minn., U. S. A., Secretary-General.

INTERNATIONAL CONGRESS OF ORTHOPEDIC SURGERY AND TRAUMATOLOGY, Berne, Switzerland, Aug. 30-Sept. 3, 1954. For information write: Professor M. Dubois, Isle-Hospital, Berne, Switzerland.

LATIN AMERICAN CONGRESS ON MENTAL HEALTH, Sao Paulo, Brazil, July 17-22. For information address: Professor A. C. Pacheco e Silva, Avenida Brigaderio Luiz Antonio 651, Sao Paulo, Brazil.

LATIN AMERICAN CONGRESS OF OTORHINOLARYNGOLOGY, Caracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro, Medico, Caracas, Venezuela, Secretary-General.

PAN AMERICAN CONGRESS OF CHILD WELFARE AND PEDIATRICS, Sao Paulo, Brazil, July 15-21, 1954. For information address: Dr. Jairo Ramos, Avenida Brigaderio Luiz Antonio 278-8º andar, Sao Paulo, Brazil.

PAN AMERICAN CONGRESS OF GASTROENTEROLOGY, Sao Paulo, Brazil, July 19-24, 1954. For information address: Dr. Jairo Ramos, Avenida Brigaderio Luiz Antonio 278-8º andar, Sao Paulo, Brazil.

PAN AMERICAN CONGRESS OF OPHTHALMOLOGY (Interim), São Paulo, Brazil, June 17-21, 1954. Dr. Moacyr E. Alvaro, Consolacao 1151, São Paulo, Brazil, President.

PAN AMERICAN CONGRESS OF OTORHINOLARYNGOLOGY AND BRONCHESOPHAGOGY, Mexico, D.F., Mexico, Feb. 28-March 4, 1954. Dr. Maximo Garcia Castañeda, Humboldt 17, Mexico 1, D.F., Mexico, Secretary-General.

PAN AMERICAN CONGRESS OF VETERINARY MEDICINE, Sao Paulo, Brazil, April 3-10, 1954. Dr. Joao Soares Veiga, Rua Pires da Mota 159, Sao Paulo, Brazil, Chairman of Organizing Committee.

PAN-PACIFIC SURGICAL CONGRESS, Honolulu, Hawaii, Oct. 7-18, 1954. Dr. F. J. Pinkerton, Suite 7, Young Bldg., Honolulu 13, Hawaii, Director General.

SECTIONAL MEETING, AMERICAN COLLEGE OF SURGEONS, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

SOUTH AMERICAN CONGRESS OF ANGIOLOGY, Sao Paulo, Brazil, July 1954. For information write: Dr. Rubens Carlos Mayall, Rua Senador Vergueiro 73, Rio de Janeiro, Brazil, S. A.

WORLD CONGRESS OF CARDIOLOGY, Washington, D. C., and Bethesda, Md., U. S. A., Sept. 12-17, 1954. Dr. L. W. Gorham, 44 East 23d St., New York 10, N. Y., U. S. A., Secretary-General.

WORLD CONGRESS OF INTERNATIONAL SOCIETY FOR THE WELFARE OF CRIPPLES, Scheveningen-The Hague, Netherlands, Sept. 13-17, 1954. Secretariat: Miss H. P. Post, Pieter Lastmarkade 37, Amsterdam Z, Netherlands.

WORLD FEDERATION OF OCCUPATIONAL THERAPISTS, Edinburgh, Scotland, August 17, 1954.

WORLD MEDICAL ASSOCIATION, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination*. Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

ARKANSAS:* *Examination*. Little Rock, June 10-11. Sec., Dr. Joe Verser, Harrisburg, *Eclectic*. Little Rock, June 11-12. Sec., Dr. O. L. Atkinson, 2528 Central Ave., Hot Springs National Park.

CALIFORNIA: *Written*. Los Angeles, March 15-18; San Francisco, June 21-24; San Diego, Aug. 23-26; Sacramento, Oct. 18-21. *Oral*. Los Angeles, March 13; San Francisco, June 19; San Diego, Aug. 21; Los Angeles, Nov. 20. *Oral and Clinical Examination for Foreign Medical School Graduates*. Sec., Dr. Louis E. Jones, 1020 N Street, Sacramento.

COLORADO:* *Examination*. Denver, June 8-9. Final date for filing applications is May 8. *Reciprocity*. Denver, April 13. Final date for filing applications is March 13. Exec. Sec., Mrs. Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

CONNECTICUT:* *Examination*. Hartford, March 9-10. Secretary to the Board, Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic*. Derby, March 9-10. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

DISTRICT OF COLUMBIA:* *Examination*. Washington, May 10-11. Deputy Director, Mr. Paul Foley, Department of Occupations and Professions, 1740 Massachusetts Ave., N.W., Washington, D. C.

FLORIDA:* *Examination*. Jacksonville, June 27-29. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami.

GEORGIA: *Examination and Reciprocity*. Atlanta and Augusta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

GUAM: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agaña.

ILLINOIS: *Examination and Reciprocity*. Chicago, April 6-8; June 22-24, and Oct. 5-7. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

INDIANA: *Examination*. Indianapolis, June 16-18. Exec. Sec., Miss Ruth V. Kirk, 538 K of P Bldg., Indianapolis.

IOWA:* *Examination*. Iowa City, June 14-16. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

KANSAS: *Examination and Reciprocity*. Kansas City, June 9-10. Sec., Dr. O. W. Davidson, 872 New Brotherhood Bldg., Kansas City.

KENTUCKY: *Examination*. Louisville, June 7-9. Address Mr. Raymond F. Nixon, Ass.-tant Secretary, 620 S. 3rd St., Louisville 2.

MAINE: *Examination and Reciprocity*. Portland, March 9-10. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Examination and Reciprocity*. Baltimore, June 15-18. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore 1.

MICHIGAN:* *Examination*. Detroit and Ann Arbor, June 1954. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

MISSISSIPPI: *Examination and Reciprocity*. Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Old Capitol, Jackson 113.

MONTANA: *Reciprocity*. Helena, April 5. *Examination*. Helena, April 6-7. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

NEBRASKA:* *Examination*. Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

NEW HAMPSHIRE: *Examination and Reciprocity*. Concord, March 10. Sec., Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination*. Trenton, June 15-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO:* *Examination and Reciprocity*. Santa Fe, April 12-13. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

OHIO: *Examination*. Columbus, June 14-16. *Reciprocity*. Columbus, April 13. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA:* *Examination*. Oklahoma City, June 9-10. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

SOUTH DAKOTA:* *Reciprocity* can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

TENNESSEE:* *Examination*. Memphis, March 24-25. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

TEXAS: *Examination and Reciprocity*. Fort Worth, June 21-23. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Ft. Worth 2.

VIRGINIA: *Examination and Reciprocity*. Richmond, June 16. Address: Virginia Board of Medical Examiners, 631 First St., S.W., Roanoke.

ALASKA:* On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

PUERTO RICO: *Examination*. Santurce, March 2-6. Sec., Mr. Joaquin Mercado-Cruz, Box 9156, Santurce.

VIRGIN ISLANDS: *Examination*. St. Thomas, June 9-10. Sec., Dr. Earle M. Rice, St. Thomas.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity*. On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARIZONA: *Examination*. Tucson, March 16. Sec., Mr. Herbert D. Rhodes, University of Arizona, Tucson.

ARKANSAS: *Examination*. Little Rock, May 3-4. Sec., Mr. Louis E. Gebauer, 1002 Donaghey Bldg., Little Rock.

COLORADO: *Examination*. Denver, March 3-4. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

FLORIDA: *Examination*. Gainesville, June. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

NEBRASKA: *Examination*. Omaha, May 4-5. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln 9.

OKLAHOMA: *Examination*. Oklahoma City, April 16-17. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination*. Portland, March 6, June 5, Sept. 11 and Dec. 4. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

SOUTH DAKOTA: *Examination*. June 11-12. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: *Examination*. Memphis, March 17-18. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

TEXAS: *Examination*. April 1954. Location determined by number of applicants from different sections of the state. Sec., Brother Raphael Wilson, C.S.C., 407 Perry-Brooke Bldg., Austin.

WISCONSIN: *Examination*. Madison, April 3 and June 5. Final date for filing application is March 26 and May 28. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

*Basic Science Certificate required.

DEATHS

McLester, James Somerville * Birmingham, Ala., 88th President of the American Medical Association and for many years chairman of its Council on Foods and Nutrition, died Feb. 8, aged 77. Dr. McLester was born in Tuscaloosa, Ala., Jan. 25, 1877. He obtained his collegiate education at the University of Alabama, where he received his bachelor of arts degree in 1896. In 1899 he was granted his degree of doctor of medicine at the University of Virginia Department of Medicine in Charlottesville. This was followed by postgraduate studies at the universities of Göttingen and Freiburg in Germany, from which he returned in 1902 to become professor of pathology in the Birmingham Medical College. Within a few years his title was changed to professor of medicine, and he began the practice of internal medicine in Birmingham. In 1907 and 1908 he took further postgraduate work in Berlin and Munich. The Birmingham Medical College was discontinued in 1912, and for a few years Dr. McLester was not actively engaged in teaching. After the establishment of a school of the medical sciences at the University of Alabama, he was appointed professor of medicine in 1919 and remained in that position for many years. Dr. McLester had a prominent part in organizing a four year medical school at the University of Alabama in Birmingham, from which the first class was graduated in 1946. At the time of his death he held the title of professor emeritus of medicine. In World War I was commissioned a major in the medical service, and early in 1918 he was promoted to lieutenant colonel in the American Expeditionary Forces, becoming commanding officer of Evacuation Hospital no. 18. On his return from military service in 1919 he resumed practice in Birmingham and became professor of medicine in the University of Alabama School of Medical Sciences. During World War II he was chairman of the subcommittee on nutrition of the National Research Council, which committee was concerned with the feeding of the armed forces. He was also a member of the Food and Nutrition Board of this council. Dr. McLester was secretary of the Section on Practice of Medicine of the American Medical Association in 1917 and 1918, and chairman of this section at the annual session in 1920. He served as a member of the House of Delegates from the Section on Practice of Medicine in 1921, and again from 1929 to 1933. In 1929 he became a member of the Council on Medical Education and Hospitals, serving until his election as President of the American Medical Association in 1934. Since 1933 he was a member of the Committee on Foods (later the Council on Foods and Nutrition) of the Association (with the exception of the two years of his Presidency) and chairman from 1940 to 1952. The Board of Trustees of the American Medical Association, through its Council on Foods and Nutrition, on Nov. 28, 1953, awarded him the Joseph Goldberger award for outstanding contributions in the field of clinical nutrition. Dr. McLester was thus cited for his outstanding role in translating the results of nutrition research into human values and in the integration of nutrition into the teaching of

all phases of medicine. A specialist certified by the American Board of Internal Medicine, he was associated with many scientific societies, being a fellow and past regent of the American College of Physicians, a member of the Association of American Physicians, the Society of Clinical Investigation, the American Climatological and Clinical Association, and the Southern Medical Association. In 1920 he was president of the Alabama State Medical Association and in 1910 president of the Jefferson County Medical Society. He served as chairman of the health advisory council of the Chamber of Commerce of the United States and as a member of the general advisory committee of the National Foundation for Infantile Paralysis. From 1928 to 1935 he was a member of the State Board of Censors and State Board of Health. Dr. McLester was medical director of the Birmingham public schools and on the staff of the Hillman Hospital for many years. He wrote "Nutrition and Diet in Health and Disease," now in its sixth edition, and "The Diagnosis and Treatment of Disorders of the Metabolism." He also wrote the chapter on diseases of the mediastinum in the Oxford System of Medicine and the chapter on syphilis in Cecil's textbook of medicine.

Guess, Harry Carl * Buffalo; University of Buffalo School of Medicine, 1912; member of the House of Delegates of the American Medical Association, 1941 and 1942; past president of the Medical Society of Erie County; member of the American Proctologic Society; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery and the American Board of Proctology; member of the board of trustees of the Western New York Medical Plan; instructor in proctology at his alma mater; since 1939 physician to the Alcoholic Beverage Control Board; member of the publication committee of the *Erie County Medical Bulletin*; on the staffs of the Sisters of Charity Hospital, E. J. Meyer Memorial Hospital, and Lafayette General Hospital; chairman, department of proctology, Millard Fillmore Hospital, where

JAMES SOMERVILLE MCLESTER, M.D., 1877-1954

he was past president of the staff and where he died Dec. 2, aged 65, of coronary occlusion.

Craster, Charles Vaughan, East Orange, N. J.: born in Middlesbrough, Yorkshire, England, April 15, 1877; L.R.C.P., Edinburgh, Scotland, L.R.C.S., Edinburgh, and L.F.P.S., Glasgow, Scotland, 1902; D.P.H., Cambridge, England, 1906; in 1909 went to New York as research assistant in pathology at Columbia University College of Physicians and Surgeons; later while at Rosebank, Staten Island, served as bacteriologist in the New York State Health Department Quarantine Service; health officer of the city of Newark from 1915 to Aug. 16, 1951, when he retired; organized Essex County Health Officers Association; past president of the New Jersey Health Officers Association, New Jersey Health and Sanitary Association, and the International Medical Health Officers Association; fellow of the American Public Health Association; major, U. S. Medical Officers Reserve Corps; died Dec. 7, aged 76, of carcinoma of the bladder.

* Indicates Member of the American Medical Association.

Barry, Lee Willis ☉ St. Paul; born in Elbridge, Mich., in 1886; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1911; clinical assistant professor of obstetrics and gynecology at the University of Minnesota Medical School in Minneapolis; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; member of St. Paul Surgical Society, Minnesota Academy of Medicine and St. Paul Clinical Club; served as a contract surgeon in the U. S. Army during World War I; affiliated with the Fairview Hospital in Minneapolis, Ancker, Charles T. Miller, St. Joseph's, and St. Luke's hospitals; received his Ph.D. degree in obstetrics and gynecology in 1919 from the University of Minnesota; died in Fort Lauderdale, Fla., Dec. 3, aged 67, of myocardial infarction.

Judd, Albert Martin, Brightwaters, N. Y.; born in 1870; College of Physicians and Surgeons, medical department of Columbia College, New York, 1893; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; formerly clinical professor of gynecology at the Long Island College Hospital, Brooklyn; consulting obstetrician and gynecologist, Kings County Hospital, Brooklyn, and Rockaway Beach (N. Y.) Hospital; consulting gynecologist, Jewish and Swedish hospitals in Brooklyn; consulting obstetrician, Wyckoff Heights and Coney Island hospitals and Norwegian Lutheran Deaconesses' Home and Hospital in Brooklyn, and Flushing (N. Y.) Hospital and Dispensary; died recently, aged 83, of cerebral vascular hemorrhage.

Werner, August Anthony ☉ St. Louis; born in Newton, Kan., Jan. 30, 1883; St. Louis University School of Medicine, 1911; assistant professor of internal medicine at his alma mater; specialist certified by the American Board of Internal Medicine; member of the Endocrine Society, Society of Experimental Biology and Medicine, Southern Medical Association, and the American Association for the Advancement of Science; fellow of the American College of Physicians; served on the staffs of the State Hospital No. 4 in Farmington, Missouri Baptist Hospital, St. John's Hospital, and St. Mary's Group of Hospitals; author of "Endocrinology: Clinical Application and Treatment"; died Dec. 20, aged 70, of injuries received in an automobile accident.

Gray, Charles Perley ☉ New York City; born Jan. 31, 1875; Harvard Medical School, Boston, 1904; adjunct professor of gynecology and obstetrics at New York Polyclinic Medical School and Hospital; fellow of the American College of Surgeons; served during the Mexican border conflict and World War I; past president of the University Alumni Association of New York and of Harvard Medical Society; member of the Association of Military Surgeons of the United States and the Seventh Regiment Veterans Association; served on the staffs of Midtown and City hospitals, the North East Dispensary and Wickersham Hospital where he died Dec. 8, aged 78, of heart disease.

Felton, Lloyd Derr, medical director, U. S. Public Health Service, retired, Bethesda, Md.; born in Pine Grove Mills, Pa., in 1885; Johns Hopkins University School of Medicine, Baltimore, 1916; member and formerly councilor of the Society of American Bacteriologists; member of the American Public Health Association; before joining the U. S. Public Health Service as senior surgeon, was connected with Johns Hopkins in Baltimore and Harvard in Boston, as well as the Rockefeller Institute for Medical Research; medical director of the National Institutes of Health from 1944 until his retirement in 1949; died Sept. 11, aged 67.

Wynkoop, Edward Judson ☉ Syracuse, N. Y.; born in Syracuse April 24, 1869; Syracuse University College of Medicine, 1892; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; professor emeritus of pediatrics at his alma mater; past president of the Onondaga County Medical Society; served during World War I; supervising physician of the Onondaga County Welfare Department; on the staff of the Hospital of the Good Shepard; consulting pediatrician at University Hospital, and the Free Dispensary; senior pediatrician at Memorial Hospital, where he died Dec. 17, aged 84.

Stratton, Frederick Alexander ☉ Milwaukee; born in 1880; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; clinical professor emeritus of surgery at the Marquette University School of Medicine; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; past president of the Milwaukee County Medical Society; consulting surgeon, Milwaukee County Hospital in Wauwatosa, and Columbia and Johnston Emergency hospitals; chief surgeon on the staff of St. Joseph's Hospital; died in Shorewood, Wis., Jan. 13, aged 73, of cerebral hemorrhage.

Noll, Joseph Emerson ☉ Port Jervis, N. Y.; born in Port Jervis, May 11, 1893; University and Bellevue Hospital Medical College, New York, 1917; specialist certified by the American Board of Radiology; member of the American College of Radiology; fellow of the American College of Surgeons; past president of the Orange County Medical Society; president of the New York State Association for Crippled Children; director of the Cooperative Loan and Savings Bank; served during World Wars I and II; on the staffs of St. Francis Hospital in Port Jervis and Alexander Linn Hospital in Sussex, N. J.; died Dec. 3, aged 60, of coronary thrombosis.

Arnold, Isaac Albert ☉ Louisville, Ky.; born in 1883; University of Louisville (Ky.) Medical Department, 1907; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; instructor in general surgery at his alma mater from 1919 to 1923, from 1923 to 1927 clinical instructor in surgery, and from 1927 to 1939 associate professor of surgery; served overseas during World War I; consultant at the Norton Memorial Infirmary, where he was president of the staff in 1943 and where he died Dec. 3, aged 70, of myocarditis.

von Zelinski, Walter Franz ☉ Col., U. S. Army, retired, Santa Barbara, Calif.; born July 16, 1882; Bennett Medical College, Chicago, 1908; served during World Wars I and II; entered the regular army as a major Sept. 11, 1920; promoted to colonel June 2, 1943; retired Sept. 30, 1945; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the International College of Surgeons and the American College of Surgeons; affiliated with Santa Barbara Cottage Hospital; died Dec. 26, aged 71, of auricular fibrillation and cardiac hypertrophy.

Hodge, James Vernon ☉ Kingsport, Tenn.; born Oct. 31, 1889; Lincoln Memorial University Medical Department, Knoxville, 1914; specialist certified by the American Board of Otolaryngology; past president of the Sullivan-Johnson Counties Medical Society; member of the American Academy of Ophthalmology and Otolaryngology and the Tennessee Academy of Ophthalmology and Otolaryngology, of which he was vice-president; for many years member of the board of education; affiliated with Holston Valley Community Hospital; died Nov. 30, aged 64, of cancer.

Plaggemeyer, Harry Ward ☉ Detroit; Johns Hopkins University School of Medicine, Baltimore, 1907; associate professor of clinical urology at Wayne University College of Medicine; specialist certified by the American Board of Urology; served during World War I; past president of the Wayne County Medical Society; member of the American Urological Association; fellow of the American College of Surgeons; affiliated with the City of Detroit Receiving Hospital and the Grace Hospital, where he died Dec. 19, aged 72, of dissecting aneurysm with pericardial hemorrhage and hypertension.

Witte, Max Ernest ☉ Independence, Iowa; State University of Iowa College of Medicine, Iowa City, 1920; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association and the New England Society of Psychiatry; in 1912 member of the House of Delegates of the American Medical Association; served overseas during World War II; formerly affiliated with the Bangor (Maine) State Hospital and the Maine General Hospital in Portland; superintendent of the Independence State Hospital; died Nov. 12, aged 58, of a coronary attack.

Elmer, Warren Philo * St. Louis; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; associate professor emeritus of clinical medicine, Washington University School of Medicine; for many years on the faculty of St. Louis University School of Medicine; specialist certified by the American Board of Internal Medicine; consultant to the Missouri Pacific Lines; joint author of "Elmer and Rose Physical Diagnosis"; on the staff of the Barnes Hospital; physician in charge of Missouri Pacific Hospital, where he died Dec. 27, aged 74, of coronary thrombosis.

Bach, Luther * Florence, Ky.; University of Louisville (Ky.) School of Medicine, 1915; fellow of the American College of Physicians; past vice-president of the Kentucky State Medical Association; veteran of World War I; trustee and one of the founders of Magoffin Institute at Mount Valley; member of staff, St. Elizabeth and William Booth Memorial Hospital in Covington; consultant, Speers Memorial Hospital in Dayton; died Nov. 28, aged 62, of arteriosclerotic heart disease.

Baird, Charles Glenn * Palo Alto, Calif.; St. Louis University School of Medicine, 1912; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; served during World Wars I and II; affiliated with the Veterans Administration in San Francisco; died in the Veterans Administration Hospital in San Francisco Dec. 3, aged 66, of Hodgkin's disease.

Barber, Oliver Stillman * Creston, Iowa; Kansas City (Mo.) Medical College, 1896; Rush Medical College, Chicago, 1897; died in La Grange, Ill., Nov. 15, aged 78.

Barland, Samuel Shay * Elmhurst, N. Y.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1929; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; affiliated with Queens General Hospital and the Memorial Hospital in Jamaica, Parsons Hospital in Flushing, and the Bethany Deaconess Hospital in Brooklyn; died Nov. 27, aged 48, of acute coronary occlusion.

Belitz, Alfred E., * Pepin, Wis.; College of Physicians and Surgeons of Chicago, 1895; died in Wabasha, Minn., Nov. 9, aged 87, of pulmonary emboli.

Berkowitz, Charles * Chicago; Northwestern University Medical School, Chicago, 1930; assistant professor of medicine at the Chicago Medical School; affiliated with the Winfield (Ill.) Hospital and the Mount Sinai Hospital, where he died Jan. 11, aged 48, of cerebral hemorrhage.

Blankingship, Oliver F. * Gordonsville, Va.; Medical College of Virginia, Richmond, 1891; died Oct. 18, aged 86, of coronary thrombosis.

Blau, Albert * Elmhurst, N. Y.; Medizinische Fakultät der Universität, Vienna, Austria, 1899; died Jan. 4, aged 79, of heart failure.

Booher, Wayne Emerson * Waynesburg, Pa.; Western Reserve University Medical Department, Cleveland, 1912; affiliated with the Greene County Memorial Hospital; for many years on the staff of Western Pennsylvania Hospital in Pittsburgh; died in the Presbyterian Hospital, Pittsburgh, Dec. 14, aged 69, of uremia and carcinoma of the prostate.

Bowman, Charles Leon * Pittsburgh; University of Pittsburgh School of Medicine, 1908; fellow of the American College of Surgeons; practiced in Mount Oliver, where he was president of the board of health, and school physician; on the staff of South Side Hospital; died in St. Joseph's Hospital Dec. 14, aged 72, of cancer of the prostate.

Broadbent, Oliver Pickering * Jacksonville, Fla.; Indiana University School of Medicine, Indianapolis, 1924; member of the American Academy of General Practice; died Nov. 22, aged 59, of acute coronary thrombosis.

Bryan, Guy Sanford, Greenville, Miss.; Memphis (Tenn.) Hospital Medical College, 1909; died in Yazoo City Jan. 1, aged 70.

Buck, Leonard William * San Francisco; University of California Medical School, San Francisco, 1928; specialist certified by the American Board of Pathology; member of the College of American Pathologists; lecturer and curator at his alma mater; died Dec. 23, aged 62.

Burnham, James P., Canton, Miss.; Memphis (Tenn.) Hospital Medical College, 1906; died Dec. 24, aged 81.

Carpenter, Thomas Alan, Chicago; Chicago Medical School, 1928; died in Grant Hospital Jan. 7, aged 66, of arteriosclerotic heart disease.

Clark, Guy W., Bertrand, Neb.; Creighton University School of Medicine, Omaha, 1904; died in the Brewster Hospital in Holdrege Oct. 27, aged 80, of arteriosclerosis and uremia.

Copeland, Joseph Walter, Leland, Miss. (licensed in Mississippi in 1907); killed Jan. 7, aged 82, when the automobile in which he was driving was struck by a train.

Cotter, Lawrence Edward * Red Hook, N. Y.; Fordham University School of Medicine, New York, 1913; Dutchess County medical examiner; on the courtesy staff of Northern Dutchess Health Service Center, in Rhinebeck, and St. Francis and Vassar Brothers hospitals in Poughkeepsie; died Dec. 25, aged 65, of a coronary attack.

Cox, Shelby L., Water Valley, Miss.; Memphis (Tenn.) Hospital Medical College, 1901; died Dec. 26, aged 76.

Craddock, James Edward * Louisville, Ky.; University of Louisville (Ky.) School of Medicine, 1932; served during World War II; affiliated with St. Joseph Infirmary, St. Anthony's Hospital, and Louisville General Hospital, where he died Dec. 11, aged 46, of burns suffered in an explosion during a barbecue in his back yard.

Dormody, Hugh Frederick * Monterey, Calif.; University of California Medical School, San Francisco, 1922; member of the Industrial Medical Association; past president of the Monterey County Medical Association; served as a member of the city council and as mayor; co-founder of the Monterey Hospital; died in the University of California Hospital, San Francisco, Dec. 20, aged 58, of hepatitis and postoperative gastrointestinal hemorrhage.

Douglas, Jean Smith, Wooster, Ohio; University of Pittsburgh School of Medicine, 1911; died in Apple Creek Nov. 9, aged 70.

Elsay, Edward McClintock * Glenwood, Minn.; University of Minnesota Medical School, Minneapolis, 1929; affiliated with Glenwood Community Hospital; killed near Black Duck Nov. 14, aged 50, when he was accidentally shot while deer hunting.

Faus, Ralph Warren * Wellington, Ohio; Cleveland-Pulte Medical College, 1914; died Nov. 9, aged 61, of coronary occlusion.

Flesher, Thomas Harrison * Edmond, Okla.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901; city health officer; college physician for Central State College; on the associate staff of Wesley Hospital in Oklahoma City, where he died Dec. 20, aged 77, of acute lymphatic leukemia.

Ford, Clyde Sinclair * Col., U. S. Army, retired, Sarasota, Fla.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1894; served during the Spanish-American War and World War I; entered the medical corps of the U. S. Army January, 1899; promoted through the various grades to that of lieutenant colonel May 15, 1917; retired Nov. 20, 1920 for disability in line of duty; retired as a colonel June 21, 1930 under the act of June 21, 1930; died Dec. 29, aged 86, of internal hemorrhage.

Gerety, William Francis * Danville, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; on the staff of St. Elizabeth Hospital; died Dec. 28, aged 70, of coronary thrombosis.

Goldey, Jacob * New York City; Bellevue Hospital Medical College, New York, 1895; for many years associated with the city health department; died Dec. 28, aged 82.

Gulde, Andros ⊕ Chelsea, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; for many years director of the Chelsea State Bank; died Dec. 22, aged 79, of a heart attack.

Hardin, Thomas Lee ⊕ St. Charles, Mo.; Barnes Medical College, St. Louis, 1896; an Associate Fellow of the American Medical Association; for many years president of the board of education; affiliated with St. Joseph's Hospital, where he died Dec. 9, aged 80, of fracture of the hip, received in a fall, and renal insufficiency with uremia.

Held, Alvin Theodore ⊕ Decatur, Ill.; Harvard Medical School, Boston, 1944; interned at St. Luke's Hospital in Chicago, where he served a residency; certified by the National Board of Medical Examiners; a flight surgeon during World War II; on the staffs of Decatur and Macon County Hospital and St. Mary's Hospital; died Dec. 8, aged 34.

Hendren, Silas Edwards ⊕ Dayton, Ohio; Ohio Medical University, Columbus, 1900; affiliated with St. Elizabeth Hospital; died Nov. 23, aged 81, of cerebral hemorrhage.

Holm, Hillard Herman ⊕ Glencoe, Minn.; University of Minnesota Medical School, Minneapolis, 1919; fellow of the American College of Surgeons; affiliated with Glencoe Municipal Hospital; died in Minneapolis Nov. 19, aged 60, of gastrointestinal hemorrhage.

Ingleright, Leon R., Niles, Mich. (licensed in Michigan in 1901); died Oct. 27, aged 83, of cerebral vascular accident.

James, Howard Stanley ⊕ Cincinnati; Miami Medical College, Cincinnati, 1907; died in the Christ Hospital Dec. 20, aged 73, of intestinal obstruction, volvulus, and old duodenal ulcer.

Jones, Guy Walter Stanley ⊕ New Bedford, Mass.; Tufts College Medical School, Boston, 1914; affiliated with Acushnet and Union hospitals; died in St. Luke's Hospital Dec. 3, aged 70, of myocardial infarction.

Jones, Samuel Houston Sr., Sunbright, Tenn.; Vanderbilt University School of Medicine, Nashville, 1900; formerly member of the county board of education; burned to death in a fire that destroyed his residence Dec. 14, aged 79.

Kelly, Delbert Cleo, Astoria, Ore.; University of Illinois College of Medicine, Chicago, 1940; served during World War II; formerly county health officer; died in the Veterans Administration Hospital in Portland Dec. 2, aged 42, of cirrhosis of the liver and homologous serum jaundice.

Kickham, Charles Joseph ⊕ Boston; Tufts College Medical School, Boston, 1908; member of the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; formerly vice-president of the Massachusetts Medical Society; past president of the Norfolk County Medical Association; served as a member of the House of Delegates of the American Medical Association from 1945 through 1951; for many years affiliated with St. Elizabeth's Hospital; died Jan. 4, aged 68, of coronary thrombosis.

King, William Russell ⊕ Tennille, Ga.; Atlanta College of Physicians and Surgeons, 1912; died Dec. 9, aged 64.

Marr, James Jr., ⊕ Grafton, N. D.; St. Louis University School of Medicine, 1927; member of the Iowa State Medical Society; formerly member of the staff of the Glenwood (Iowa) State School; superintendent of the Grafton State School; died Dec. 2, aged 52, of coronary occlusion.

Moffett, James E., Silsbee, Texas; Memphis (Tenn.) Hospital Medical College, 1908; died Dec. 11, aged 68, of coronary thrombosis.

North, Charles Quay ⊕ Seattle; University of Pennsylvania School of Medicine, Philadelphia, 1916; specialist certified by the American Board of Otolaryngology; served during World Wars I and II; died in Redondo, Wash., Dec. 29, aged 65, of coronary thrombosis.

Outlaw, Frank Calhoun, Woodlawn, Tenn.; Vanderbilt University School of Medicine, Nashville, 1891; died Dec. 23, aged 91.

Patterson, Lawrence Leslie ⊕ Kapaa, Hawaii; Denver and Gross College of Medicine, 1909; served during World War I; formerly member of the legislature; died Dec. 15, aged 68.

Phelan, George Warren, Brooklyn; McGill University Faculty of Medicine, Montreal, Canada, 1913; assistant professor of clinical obstetrics and gynecology at State University of New York College of Medicine at New York City; served during World War I, and received the British Military Cross; on the staffs of the St. John's Episcopal Hospital and the Long Island College Hospital, where he died Dec. 31, aged 65, of coronary thrombosis.

Post, Arthur T., ⊕ Clarksburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1907; past president of the Harrison County Medical Society; served on the staffs of the Union Protestant Hospital and St. Mary's Hospital; died Jan. 8, aged 73, of coronary thrombosis.

Rhomberg, Edward Bideaux, Guttenberg, Iowa; Loyola University School of Medicine, Chicago, 1930; served during World War II; affiliated with Xavier Hospital, Finley Hospital, and Mercy Hospital in Dubuque, where he died Dec. 18, aged 50, of coronary thrombosis.

Russell, Edmund David, Milwaukee; State University of Iowa College of Medicine, Iowa City, 1896; died in Milwaukee County Hospital in Wauwatosa, Wis., Dec. 27, aged 93, of bronchopneumonia.

Sawyer, Prince Edwin ⊕ Sioux City, Iowa; State University of Iowa College of Medicine, Iowa City, 1895; fellow of the American College of Surgeons; past president of the Iowa State Medical Society; on the staff of St. Joseph Mercy Hospital; died Jan. 17, aged 79.

Shippen, Lloyd Parker, Washington, D. C.; University of Pennsylvania Department of Medicine, Philadelphia, 1907; died Dec. 29, aged 74.

Stueber, Paul Jacob ⊕ Lima, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Lima Memorial Hospital and St. Rita's Hospital, where he died Dec. 22, aged 67, of hypertensive heart disease.

Sutter, Frances Roush, Shelby, Ohio; Laura Memorial Woman's Medical College, Cincinnati, 1896; died in the Sawyer Sanatorium in Marion Nov. 1, aged 82, of cerebral hemorrhage.

Turner, Charles Sampson ⊕ Cranston, R. I.; Harvard Medical School, Boston, 1906; an Associate Fellow of the American Medical Association; died Nov. 9, aged 75, of pulmonary tuberculosis.

Underhill, Samuel Graham, Santa Barbara, Calif.; Harvard Medical School, Boston, 1901; served during World War I; formerly superintendent of the Lynn (Mass.) Hospital; died Dec. 31, aged 78; of cerebral vascular accident, hypertension, and arteriosclerosis.

Warntz, Ralph Eugene ⊕ Nescopeck, Pa.; Syracuse University College of Medicine, 1907; past president of the Columbia County Medical Society; died in the Berwick (Pa.) Hospital Nov. 13, aged 71, of congestive heart failure and diabetes mellitus.

Wittliff, Jack Stanley, Astoria, Ore.; University of Oregon Medical School, Portland, 1949; interned at Providence Hospital, Portland; served during World War II; later served in Korea, died in Portland Dec. 9, aged 31.

Zerbst, George Henry ⊕ Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1924; served as health officer of the Clarendon-Sumter District Health Department, health officer of Lee and Lexington counties, and as director of the division of industrial health for the state board of health; worked with the Veterans Administration on the Veterans Rating Board; died Nov. 21, aged 61, of acute coronary thrombosis.

GOVERNMENT SERVICES

ARMY

Doctor Draft Registrants May Be Reassigned to Ready Reserve Units.—Major Gen. George E. Armstrong, the Surgeon General, announces that reserve physicians and dentists who are not currently under orders for active military duty may join the Ready Reserve Units of the Army Medical Service. This will be accomplished by permitting the special registrants under the "Doctor-Draft" act and others who are in a U. S. Army Reserve Control Group to be transferred immediately to fill an authorized vacancy in a Ready Reserve Unit. Formerly, such a reassignment was prohibited prior to the completion of a tour of extended active duty. Although transferred, the officer will still be subject to an order to active duty without his consent as a person classified under the doctor draft and will be subject, too, to an order to active duty as a member of the unit. The transfer is entirely voluntary and will be made only if the physician or dentist so desires. An estimate of the possible numbers available for such reassignment totals more than 900 Medical Corps officers and 183 Dental Corps officers.

PUBLIC HEALTH SERVICE

Estimated Death Rate for 1953.—Despite a relatively severe influenza outbreak in January and February, the United States death rate for 1953 remained at the low level of 9.6 per thousand population, according to a preliminary estimate by the Public Health Service. This low rate has been achieved in only two previous years, 1950 and 1952, though the rate has been less than 10 deaths per thousand population since 1948.

Total deaths in the United States in 1953 were estimated at 1,523,000, based on monthly reports to the National Office of Vital Statistics by state registration offices. During the first two months of the year, when influenza was widespread, estimated deaths rose to 10% above 1952 levels for the same months. Increased deaths were also associated with the unusual heat waves of June and early September. During the entire summer, June through September, estimated deaths were 4% above the average of the three previous summers.

VETERANS ADMINISTRATION

Rehabilitation of Long-Term Mental Patients.—The Veterans Administration announces that its plan for the final rehabilitation and discharge of long-term mental patients through a program of paid hospital work has been so successful in the pilot study that it is being expanded for general use. The VA said the pilot program not only has resulted in the release of many long-term patients who were thought to have little chance of returning to the outside world but has brought about their discharge after they were equipped and conditioned to compete successfully under normal conditions.

Long-term patients, although medically rehabilitated, are often fearful of leaving the hospital because they have lost job skills and experience during their extended stay in the hospital. In order to bridge the gap, these patients are transferred to member-employee status so they may take necessary, unfilled hospital jobs at set wages and regular hours while they continue to live in the controlled environment of the hospital, with medical care, board, room, and recreation.

With the success of the pilot program already established, the VA has notified its 38 neuropsychiatric hospitals all over the nation that they now may institute the new rehabilitation program if they have the facilities to quarter patients as member-employees. The pilot program at the VA hospital in Perry Point, Md., is still under way. It was instituted by Dr. Peter A. Pfeffer who was manager of the hospital. He now is manager of the new neuropsychiatric hospital in Brockton, Mass., where he will expand the new rehabilitation technique.

At Perry Point, approximately 70 men, who had been hospitalized for an average of 10 years each, were given the opportunity to become member-employees. Some who previously were considered as having little chance of returning to the outside world now have regular jobs away from the hospital and are making a good adjustment as self-supporting citizens. In placing these men in jobs outside the hospital, Perry Point found it was not difficult to convince employers that the men were capable of sustained work. The careful work records maintained by the hospital, based on a regular eight-hour, five-day-week performance, were sufficient proof that the men were ready for outside employment.

Since member-employees are placed in unfilled, but necessary, hospital jobs, no increase in the personnel ceilings of the participating hospitals is needed, the VA said. That means the program may be conducted at no additional cost to the government, but with the potential saving that results from the more speedy return of mental patients to the outside world.

The VA said it considers the new rehabilitation plan as an invaluable addition to its program for hastening the recovery and ultimate economic adjustment of its mental patients, especially since this category of patients represents approximately one-half of the VA's total daily patient load.

Tuberculosis Survey of Veterans and Employees.—For the past four years, the Veterans Administration has conducted an extensive tuberculosis program among veterans. In the four year period the VA has screened 3,217,000 persons for tuberculosis. These include 2,513,000 patients and 704,000 employees, among whom 12,740 cases of active pulmonary tuberculosis and 34,470 cases of inactive pulmonary tuberculosis were discovered. The VA considers the number of new cases found and treated each month as an achievement in the nationwide campaign to bring tuberculosis under further control. In fact, the VA added, the survey has made it possible, for the first time, to keep VA installations virtually "clean" from tuberculosis infection of others. Another benefit cited as of incalculable value to the nation is that the search is turning up many cases in the early stages of tuberculosis when proper treatment has a greater chance of effecting a speedy and lasting cure.

Among the 704,000 VA employees screened, about 85% of the active tuberculosis cases discovered were in the early stages. An important by-product of the program, the VA said, is the large number of other chest diseases discovered during the survey. Nearly 91,000 other chest conditions were discovered during the last year of the survey. A minority of these cases required immediate care.

The VA said the figures also are particularly helpful in planning the most economical use of facilities for hospital treatment, outpatient care, and rehabilitation. The program is conducted in all of its hospitals, all outpatient clinics in regional offices, and among all employees.

In hospitals, a chest film is taken of each veteran on admission. If he remains a long period of time, roentgenograms are made every 12 months, or more frequently if indicated. In the outpatient clinics at regional offices, each outpatient veteran is checked roentgenographically at the time he is examined unless he has had such an examination within the previous six months.

Among employees, a chest roentgenogram is made of every person at the time of employment or when he is separated or transferred. Every employee is checked roentgenographically again at 6 to 12 month intervals, or more often if necessary. A tuberculin test (Mantoux) also is given to medical personnel at the time of employment, with a follow-up in indicated cases, including chest roentgenograms at more frequent intervals. This mass type of survey, the VA said, has proved its worth many times over and will continue to be more valuable as time goes on and new sources of infection are discovered and eliminated.

FOREIGN LETTERS

AUSTRIA

Meeting of Austrian Section of International College of Surgeons.—The Austrian section of the International College of Surgeons met in Vienna, Austria, in June, 1953. Prof. L. Schönbauer, president of the section, and Professor Finsterer, president of the International College of Surgeons, addressed the congress. Professor Schönbauer, speaking on cholecystopathy, discussed the various means of precise diagnosis and the poor results that may follow cholecystectomy. He emphasized dysfunction of the vegetative nervous system and the connections between sympathetic and parasympathetic nerve fibers. His investigations were directed toward determining whether conservative treatment of surgical intervention is best adapted to the treatment of cholecystic disease. Prof. W. Köhlmeier of Vienna spoke on important anatomic variations of the biliary passages and exhibited aberrant biliary ducts, which connected with the right hepatic duct in 55% of his autopsies, with direct communications between the gallbladder and the liver in 14%. Dr. G. Baccaglini of Verona showed a motion picture demonstrating a method and apparatus that permits visualization of the biliary passages during operation. Stones, carcinoma, or other pathological changes can be detected by this method, through techniques developed by Mallet-Guy and Mirizzi. Retrograde cholangiograms taken after choledochoduodenostomy were exhibited by Dr. R. Göttlob of Vienna. He obtained these pictures with neostigmine (Prostigmin) premedication, which constricts the bowel. Prof. F. Mandl of Vienna described his own method for preoperative visualization of the biliary passages, in which he injects a contrast medium through the skin and the liver. This facilitates differentiation of pathological conditions associated with carcinoma, cholelithiasis, and tissue damage.

Modern choice of anesthesia for the patient with a severely damaged liver was discussed by Dr. H. Bergmann of Linz, who prefers continuous high spinal anesthesia after premedication with diphenylhydantoin (Dilantin) and Phenergan (10-[2-dimethylamino-1-propyl] phenothiazine). Dr. Max Thorek of Chicago discussed his method of electrosurgical obliteration of the gallbladder. This procedure has lowered his mortality rate from 9.8 to 0.3%. The disadvantages of choledochoduodenostomy was the theme of Prof. F. Starlinger of Vienna. According to the literature, the mortality rate of this procedure is about 7%, and in his own 104 cases it was 10%. Prof. H. Kunz of Vienna stressed the value of careful exploration and flushing of the biliary passages to prevent recurrent disease. This author believes that scars, enlargement of lymph nodes, and an increase of fibrous tissue following severe inflammations are causes of secondary obstructions of the biliary passages.

Dr. O. Bsteh of Mistelbach described a case of fatal circulatory collapse, the result of compression of the portal vein, during an attempt to stop a hemorrhage in this region. Animal experiments indicate that it may be possible to delay such collapse if a preliminary bilateral vagotomy has been performed. Dr. R. Rauhs of Vienna spoke on congenital atresia of the biliary passages. He distinguished a proximal and a distal type and stated that only the proximal type is operable. If there is any indication that this condition exists in a newborn child, he advocates exploratory laparotomy. Dr. W. Lutze of Vienna reported 25 cases of rupture of the gallbladder, stating that the incidence of rupture in patients with disease of the gallbladder is 5.7%. The mortality rate is about 60% and depends on the time in which surgical intervention is carried out.

Dr. C. P. Bailey of Philadelphia presented his new operative technique, atriopexy, for closure of congenital interatrial and interatrial septal defects. He presented the pa-

tients' histories and described successful operations in 29 cases. Dr. A. N. Gorelik of New York described a procedure in which he sutures the pericardium to the heart to provide a better blood supply to the cardiac vessels and the heart itself in patients with rheumatic heart diseases. Prof. Ramirez Duanes of Guayaquil exhibited a film demonstrating radical resection of nearly all the pelvic organs, a procedure introduced by Brunshwig in the United States and employed for patients with advanced carcinoma to prolong survival. Dr. E. F. Bermann of Baltimore described the polyethylene esophagus used to replace an esophagus removed because of carcinoma. The mortality rate accompanying this new technique is about 8%. Professor Mandl and Professor Finsterer of Vienna emphasized the value of exploratory laparotomy in patients with hemorrhage of unknown origin.

CHILE

Pan-American Congress of Surgery.—The Ninth Pan-American Congress of Surgery was held in Santiago in November, under the chairmanship of Dr. Leonidas Aguirre Mac-Kay (Chile). Dr. F. de Amesti and Dr. E. Collao in discussing constrictive pericarditis stated that the disease is most prevalent in adolescents and young adults, though it may be observed in childhood. The most frequent cause is tuberculosis, which was found in about 50% of the cases and suspected in an additional 40%. It was frequently noted that in the course of treatment of tuberculosis with streptomycin Koch's bacillus disappears from the effusions; in a significant percentage of patients the histopathological manifestations of the disease are not discovered in the pericardial tissues. The calcifications observed in these patients, and the manifestations of tuberculosis in other systems, make the tuberculous origin very likely. About 10% of all the cases may be attributed to a pyogenic infection. Rheumatism does not appear to play any part in this disease. It is seen most commonly among the lower social classes. It is hoped that with the use of streptomycin, *p*-aminosalicylic acid, and isoniazid the frequency of constrictive pericarditis will decrease. The authors point out the dangers associated with giving these drugs either directly into the pericardial cavity or parenterally. Streptomycin so accelerates the production of scar tissue as to render subsequent cardiac decortication very difficult. This objection does not apply to isoniazid. It now seems advisable to perform this operation as soon as the exudative process has subsided and the first manifestations of constriction appear. The difficulties in performing the decortication, the operative mortality, and the poor results obtained are attributable to operating too late.

The cardiologist should determine the zone of greatest cardiac compression so that the surgeon may concentrate his efforts in that area; otherwise he must perform the most extensive decortication possible, including both ventricles, the apex of the heart, the auricles, and the vena caval openings. For patients who do not improve after the first operation the authors recommend a second operation about two months later.

Prof. A. Velasco (Chile) in discussing methods of diagnosis and treatment of arterial disorders of the extremities concluded that palpation of the arteries is a simple and effective procedure in spite of the fact that it gives no information about the state of the arteriocalcapillary network. The possibility of anomalies must be kept in mind. Oscillometry is a valuable diagnostic procedure but it also fails to indicate the state of the capillary network. Simple radiography is an aid to early diagnosis of arteriosclerosis in many cases. Arteriography can now be performed with little danger and gives valuable information concerning the localization and extent of the arterial involvement. In the study of vasodilatation it is a serious error

to rely on only one of the functional tests. The author uses them in the following order: basal thermometry, ambient or posterior tibial heat, anesthesia of the ulnar or common peroneal nerve, sympathetic anesthesia, test with tetraethylammonium bromide, spinal anesthesia, and finally general anesthesia. Frequently enough information is obtained from the first four of these tests, in which case the rest are not made.

The author now performs arterial ligatures only in exceptional cases, preferring arteriectomies complemented by operations on the sympathetic nervous system in most cases. At present the indications for vascular sutures may be amplified, and with anticoagulants and better surgical procedures the results are encouraging.

In analyzing the various methods of treating arterial and arteriovenous aneurysms, Velasco stated that the ideal form of therapy is endoaneurysmorrhaphy, and only in patients in whom this form of treatment is impossible does he use other techniques. A complementary regional sympathectomy is of great help. Post-traumatic arteriovenous aneurysms are much easier to treat than congenital aneurysms.

In embolism, the ischemia is the result of a combination of obstruction of the vessel and sympathetic reflex vasoconstriction. Embolism may be confused with acute thrombophlebitis. Massive gangrene of the upper extremities is rare, whereas in the lower extremities it is the rule. Embolectomy must be performed on these patients. The treatment of choice for acute thromboarteritis is early arteriectomy combined with regional sympathectomy.

The author differentiated the rare essential from the commoner symptomatic Raynaud's syndrome and stated that in the essential Raynaud's syndrome there are no organic vascular lesions unless the disease is of long standing. Treatment is successful only if the disease is due to endocrine disorders; otherwise palliative treatment is all that can be offered.

Radiography aids in the early diagnosis of arteriosclerosis, but clinical examination is a sufficient guide to prognosis and treatment. Surgical treatment is recommended for a selected group of patients. Gangrene may be prevented if the diagnosis is made at an early stage of acute thromboarteritis and arteriectomy complemented by sympathetic anesthesia or resection is performed as early as possible. If amputation becomes necessary, it should be performed at the level of the thigh, Callander's method being preferred.

Anticoagulants represent a great advance in the medical management of these patients. No really effective drug has been found to relieve the ischemia. Methanesulfonates of dihydrogenated ergotoxine alkaloids (Hydergine), acetylcholine, kallikrein (Padutin), testosterone, and vitamin E have been used with varying results. Periarterial sympathectomy is being used less and less because it provides insufficient denervation and the results obtained are inferior to those following thoracic or lumbar sympathectomy.

Dr. E. Petermann reported a series of 96 cases of traumatic hemothorax, most of which were due to penetrating injuries caused by steel weapons and a few of which were caused by firearms or closed thoracic trauma. In 29 patients the hemothorax fluid reabsorbed spontaneously. The average stay in the hospital of these 29 patients was 10 days. Thoracocentesis was performed early and as the sole treatment in 31 cases. In those cases in which repeated punctures were performed, the removed liquid did not show new hemorrhages but rather an irritative pleural exudation, and the radiological examinations revealed pleural thickening. At discharge the average decrease in vital capacity was about 18%. The average stay in the hospital of this group was 24 days. In 23 of these patients the fluid was coagulated and little or none of it could be removed by thoracocentesis, necessitating thoracotomy or pulmonary decortication. Ten patients were operated on before the 10th and eight before the 20th hospital day. In 14 the thoracotomy was performed through the intercostal space and in 9 by resection of the 6th rib. In the 10 patients operated on before the 10th day, liquid and coagulated blood and a thin network of fibrin, which was beginning to show organization, was found in the pleural cavity. In the patients operated on later,

an already organized membrane was encountered and all required decortication. In five of the patients operated on early no drain was used. At discharge from the hospital the average decrease in the vital capacity was 30%. The average stay in the hospital for this group was 43 days. Infected hemothoraxes were present in 13 patients, and in them little or no fluid could be removed by thoracocentesis. Most of these patients required pulmonary decortication; three of them had empyema and in four it was necessary to drain basal encysted empyemas secondarily. The average decrease in vital capacity was 34.3%, and the average hospital stay of this group was 60 days.

ITALY

Maternity and Child Welfare.—The second national convention of the physicians of the maternity and child welfare organization was held in Verona in October under the chairmanship of Professor Bentivoglio, University of Padua pediatric clinic. Professor Revoltella from the same university spoke of the decrease in the birth and death rates in Italy. This has led to a marked alteration in the population structure, with the proportion of older persons constantly increasing. These facts should lead to a serious investigation of the medical and social measures aimed at preventing a decrease in the birth rate and on the other hand of assuring the highest probability of survival for healthy newborn infants. Better assistance should be given to the pregnant woman and the newborn baby through well-organized medical and hospital services. Professor Revoltella also spoke of the great difference that exists today between the possibilities for obstetric assistance in northern and southern Italy. Somogy's studies indicated that the maternal mortality is less where obstetric care is possible during the delivery. In 1935 in 1 million births 116 women died from puerperal infections and 171 from other diseases of pregnancy (extrauterine pregnancy, uterine hemorrhage in pregnancy, toxemias of pregnancy, and accidents during delivery). By 1948 the mortality had decreased to 35 and 115 respectively. It is noteworthy that the prognosis for the other diseases of pregnancy has not become so favorable as that for puerperal infections, especially in rural areas.

The rate of stillbirths has increased slightly despite the work of the maternity and child welfare organization and legislation concerning maternity. Deaths occurring during the neonatal period have decreased. The causes of the stillbirths are not evident, but of greater interest to the obstetrician is the number of deaths occurring in the neonatal period because in most cases death is caused by a condition that was present before, or became present during, the delivery.

Professor Revoltella emphasized the part played by congenital weakness and prematurity in deaths in the first month of life; many deaths are due to the delivery itself and these could be prevented. A comparative study of these causes in the various regions of Italy indicated that Basilicata, Puglia, and Campania are the regions in which obstetric help is most needed. The neonatal mortality rate is especially high during the first month of life; this phenomenon should be considered with reference to (1) the influence that maternal diseases and diseases of pregnancy exert on the fetus, (2) the course of the delivery, and (3) all the factors that influence the maternal, fetal, and infant mortality. The favorable results that could be attained today have not as yet been realized in this field. Therefore, examinations by the obstetrician and the specialized physician should be encouraged during the pregnancy.

Professor Agosto stated that the infant mortality during the first year of life from 1938 to 1951 had decreased, especially for the last months of the first year of life. Deaths occurring during the first months of life are mainly caused by obstetric rather than pediatric causes. Omitting the former causes, Professor Agosto grouped the causes of death into four classes: (1) acute gastrointestinal diseases, (2) acute respiratory diseases, (3) infectious diseases, and (4) other causes excluding violence. The mortality in the first two groups has decreased markedly, while the decrease is less evident in the

other two groups although there was significant improvement. The mortality for infectious diseases and especially for bacterial diseases has decreased during the last five years. The mortality for tuberculosis has decreased only slightly and that for virus diseases has remained almost stationary. There has been a noticeable decrease in the mortality for syphilis and diseases caused by protozoa; after 1949 there were no deaths due to malaria in children in the first year of life. The mortality for tumors and diseases of the blood and the hemopoietic organs has not changed, but for all other diseases it has decreased.

Reporting on vitamins in the infant's diet, Professor Bolletti of the University of Padua said that vitamin deficiencies during the first two years are common but they are often difficult to diagnose because of the mild and nonspecific signs. The deficiency can be absolute or relative to particular conditions that through a disturbed vitamin metabolism or a greater use of vitamins produce a state in which there is a greater need for vitamins, such as living in a cold and humid climate, various debilitating diseases of long standing, and the prolonged use of some drugs.

Hypervitaminoses, on the other hand, are often not recognized by the practitioner although they are becoming more and more frequent because large doses of single vitamins are being injudiciously administered. The classic picture of hypervitaminosis D was in the past a rare phenomenon and occurred mainly when irradiated ergosterol was used, but it is becoming increasingly common because of the indiscriminate use of large doses of calciferol. This toxicosis is initially characterized by obstinate anorexia, nausea and vomiting, polyuria and polydipsia, and later by nephrotic symptoms with hyperazotemia. It is caused by an increase of the ionized fraction of the serum calcium (as was proved for the first time at the University of Padua pediatric clinic) and by calcium deposits in various organs and various tissues.

Among the various means of treatment, Professor Bolletti stressed the importance of the sodium citrate. He then discussed the two distinct syndromes that are caused by excess doses of vitamin A. One may appear a few hours after the ingestion of a very large single dose (500,000 to 700,000 units for a child) and is characterized by the sudden onset of marked signs of intracranial hypertension. The other is characterized by a slow and gradual onset secondary to prolonged use of vitamin. Its symptoms involve mainly the digestive apparatus, the liver, the skin, and the bones, in which there is a diaphysary cortical hypertrophy. The acute form subsides after administration of the vitamin is stopped. The chronic form, on the other hand, persists for a long time, and the bone manifestations regress only after several months. Among the side-effects caused by excessive doses of the vitamin B complex, Professor Bolletti cited the deaths that have been ascribed to intravenous administration of thiamine (vitamin B₁). Side-effects due to hypervitaminosis PP, C, and K are not easily recognized. He called attention to the antagonisms between lipid-soluble and water-soluble vitamins.

Dr. Panizon, also of the University of Padua, discussed the relationships between vitamins and antibiotics. He spoke of the influence that vitamin K has on the blood coagulation but said that, except for chloramphenicol, which produces a constant fall of the prothrombin time, the antibiotics do not affect clotting. As for the hemorrhage-causing effect attributed to streptomycin and *p*-aminosalicylic acid, it must be remembered that these drugs act in tissue that is already damaged.

Metabolic disorders caused by antibiotics include (1) neuritis, anemia, and glossitis due to the sulfonamides; (2) black and hairy tongue due to penicillin and streptomycin; and (3) stomatitis, gastritis, and enteritis due to chlortetracycline, chloramphenicol, and oxytetracycline. The main objection that can be made to the use of antibiotics is a reduced absorption of vitamins B₆, PP, and B₁₂, and since this secondary effect does not subside spontaneously, vitamins of the B group should be given in average doses during and after the administration of antibiotics. The metabolic advantages that derive from the use of antibiotics derive mainly from a favorable action on growth, but these advantages are mainly seen in zootechnics and experimental physiology.

LONDON

Corticotropin (ACTH) and Cortisone in Hematology.—The second report of the Medical Research Council Panel on the hematological applications of corticotropin (ACTH) and cortisone (*Brit. Med. J.* 2:1400, 1953) is based on an analysis of a further series of 65 patients, of whom 37 received cortisone; 23, corticotropin; and 5, both. The period of treatment ranged from 10 to 40 days. The total dosage ranged from 1 to 3 gm. of corticotropin and 1 to 7 gm. of cortisone, with a maximum daily dosage of 80 to 200 mg. for corticotropin and 100 to 300 mg. for cortisone. There were 10 patients with acquired hemolytic anemia (7 idiopathic and 3 symptomatic), of whom 5 showed a complete response and 3 a partial response. There was no response in one patient with congenital hemolytic anemia or in one with nocturnal hemoglobinuria. The response in 22 patients with purpura was thrombocytopenic in 15; toxic in 1; and nonthrombocytopenic in 6. One of three patients with aplastic anemia and one of two with panhematopenia had a partial response, and there was a complete response in one patient with agranulocytosis. None of the four patients with acute myeloid leukemia showed any response, and of the six with acute lymphatic leukemia one had a complete and one a partial response. There was no response in three patients with unclassified leukemia, and of five with reticulosis two had a partial and one a complete response.

A follow-up of the 88 patients included in the panel's first report (*Brit. Med. J.* 1:1261, 1952) showed that only six "appear to have improved and remained well after a single course of ACTH or cortisone"; i. e., two patients with acquired hemolytic anemia, two with idiopathic thrombocytopenic purpura, and two with toxic purpura.

Corticotropin (ACTH) and Cortisone in Nonrheumatic Conditions.—A report from Leeds (Aber, G. M., and others; *Brit. Med. J.* 1:15, 1954) gives the results obtained from the use of corticotropin (ACTH) and cortisone in nonrheumatic diseases in 43 patients. These included 14 patients with diseases of the blood. There was a favorable response in three children with acute acquired hemolytic anemia and in two patients with thrombocytopenic purpura. Of three patients with agranulocytosis, one had an excellent response, one a temporary response, and one did not respond at all. The response in three patients with myeloid leukemia was discouraging. Of 10 patients with exophthalmic ophthalmoplegia, 6 showed no improvement, 3 responded well, and 1 responded dramatically. In an attempt to explain these discrepancies in results, it was pointed out that the best results were obtained in patients whose exophthalmos was of recent origin or had suddenly and rapidly progressed. On the other hand, no response was obtained in all three patients with exophthalmos unaccompanied by weakness of the ocular muscles. The results in Simmonds' disease are summarized as follows: "The effect of ACTH in severe pituitary insufficiency has been studied in three patients, with a benefit from treatment so remarkable as to leave no room for doubt. In one patient, almost moribund on admission, the effect was lifesaving. They are now restored to useful domestic activity, though the glandular deficiency is such that continued maintenance treatment seems necessary." Two patients with virilism were treated by adrenalectomy and cortisone. In neither did the results obtained justify the risks involved. In two pseudohermaphrodites, 17-ketosteroid excretion was controlled by the use of cortisone. Their experience with two patients suffering from cirrhosis with portal hypertension indicates that "ACTH has no certain place in the present admittedly unsatisfactory attack on the problem of portal hypertension though it may remain a useful therapeutic adjuvant in the treatment of cirrhosis." Diuresis was produced in two patients with nephrosis, and in one the remission has lasted for more than a year. They confirmed the beneficial effects of cortisone and corticotropin in seven of nine patients with severe bronchial asthma: "The intravenous infusion of ACTH in normal saline seems to offer the best prospect of rapid symptomatic relief, and, together with the topical administration of cortisone by inhalation, allows of considerable economy in prescribing. The remissions induced

by these forms of treatment average one to two months, probably differing little from the duration of freedom afforded by the more usual forms of treatment."

Another Penicillin Fatality.—Another death attributed to penicillin was reported by R. C. Bell (*Lancet* 1:13, 1954). The death followed within a few minutes the injection of 300,000 units of procaine penicillin G. Within half a minute after the injection the patient, a man of 47, called out that he felt ill. His face became pale; his eyes were bloodshot; and his arms and legs became deeply cyanotic. Sticky fluid began to exude from his mouth, and well-marked signs of pulmonary edema were audible on auscultation. In spite of the administration of oxygen and nikethamide intravenously, he died in a few minutes. The significant postmortem findings were edema of the lungs, grossly edematous aryepiglottic folds, and a pink trachea. There was no previous history of allergic or hypersensitive phenomena, and the patient had previously had injections of both penicillin and of procaine, but not of procaine penicillin. The recommendation was made that "every care should be taken to avoid accidental intravenous injections of procaine penicillin G, and an antihistamine preparation should be kept at hand when this drug is being injected."

Adolescents in Adult Wards.—An investigation of the extent to which adolescents are cared for in adult wards has been made by A. C. Stuart-Clark (*Lancet* 2:1349, 1953). The inquiry, covering 3,954 beds in 195 general medical and surgical wards, revealed that 360 of the beds (9.08%) were occupied by patients between the ages of 12 and 17 years. A questionnaire was also sent to matrons and ward sisters. Of the 150 replies received, 137 felt that adolescents and adults should be cared for separately; the remainder thought they should be together. All agreed that the adolescent girl ought never to be placed in a gynecologic ward. It was generally believed that the risk of incurring fear and of exposure to unpleasant forms of conversation was greater in women's wards, because women were less careful and considerate of the younger members of the ward than men. Other objections to mixing adults and adolescents were that the latter (particularly in men's ward) tended to become spoiled if they stayed in more than a few days, and, conversely, the noise of convalescent adolescents tended to irritate the older patients. A strong preference was expressed for the provision of an adolescent annex or ward. The conclusion is reached that the replies to this questionnaire "make it clear that the percentage of adolescents in general hospital wards is substantial, and this fact, coupled with the overwhelming weight of opinion in favour of segregation expressed by those most directly connected with the life of the ward, suggests that a problem exists of sufficient size to justify fuller and more detailed consideration than has been given it hitherto."

Welfare of Epileptics and Spastics.—A report on the special welfare needs of epileptics and spastics has just been published by the Ministry of Health. It incorporates the findings and recommendations of two committees which investigated the problems of epileptics and spastics respectively. According to the former, there are at least 100,000 epileptics in England and Wales, of whom 20,000 are children of school age. This gives an incidence of at least 2 per 1,000 of population, compared with an estimated 5 per 1,000 in the United States and in Switzerland. The necessity of convincing the epileptic, his family, and friends that "his seizures do not indicate any mental deficiency; that only in so far as the actual seizures dislocate his life is he different from other people and that, apart from this, he is able to lead a normal life and, if he has reached working age, to hold down any job within his capacity" is emphasized. Recommendations were made for intensifying propaganda aimed at employers and workers to overcome their prejudice against, and superstition regarding, epilepsy. It was also recommended that all epileptic children should be brought to the notice of the school medical officer when they are two years of age. Special hostels should be established for those who are ready to try their ability in employment but who still require some care before entering or reentering the general community.

The incidence of cerebral palsy in England and Wales is estimated at between 1 and 2 per 1,000 of the school population. Of those over 15 years of age, the total is probably around 17,000 who are severely handicapped. Cerebral palsy presents a particularly difficult problem because so often there is a mental as well as a physical handicap. In dealing with psychological tests, it was pointed out that, unless these are done by persons with special experience, there is a danger that the child might be certified as mentally defective when in fact he suffers from cerebral palsy and is unable to hear or to express himself. It was concluded that a substantial number of severely handicapped spastics are written off when they attain an age to leave school and return to their homes where they draw assistance grants and come under special observation again only on the death of the parents or because of some other tragic circumstance. Local authorities are urged to consider the possibility of jointly establishing homes for the more severely handicapped adolescents and adults who are capable of some form of occupation. They are also urged to cooperate with voluntary organizations and associations of parents that have specialized in the care and welfare of spastics.

Medical Defense Union.—Presenting the report at the annual meeting of the Medical Defense Union last month, the president, Dr. S. Cochrane Shanks, commented on the increase in litigation that besets the medical profession. "In the past, a patient might hesitate to sue a voluntary hospital or a doctor who gave his services free." It is not the case now, he said. The three defense unions are at present negotiating with the Ministry on the subject, with the object of defending unwarranted actions together and of settling just claims in amicable agreement. Two committees had been set up by the council of the union during the last year—one to report on injection routine in operating theaters and the other, in conjunction with the Association of Anaesthetists, on anesthetic explosions. The first has already completed its work.

Meat Quota.—Each person in the United Kingdom is estimated to have eaten 84 lb. (38.1 kg.) of meat last year. This was 11 lb. (5 kg.) more than in 1951 but 35 lb. (15.9 kg.) below the average of 119 lb. (54 kg.) in 1938. These figures are given in a report published by the Commonwealth Economic Committee. New Zealanders, on the other hand, ate 220 lb. (99.8 kg.) per capita in 1952, or more than persons in any other major meat-producing country. This, however, was still 6 lb. (2.7 kg.) below the 1938 average for New Zealand.

PARIS

Medical Electroroentgenology.—The French Society of Medical Electroroentgenology met on June 13, 1953, to consider malignant granuloma. G. Gibert reported a series of 155 cases. He stated that the diagnosis is often made too late because of an absence of diagnostic signs early in the course of the disease. Skeletal lesions are seen in 10% of the patients. Patients with the chronic form may live for 30 years. Prolonged irradiation may produce cutaneous and visceral lesions. Fauret and Pierard, discussing acute forms and acute attacks of Hodgkin's disease, emphasized the inefficiency of the classic treatment that may even be harmful. Cortisone is only temporarily palliative. Of 246 cases treated, Lamarque, Betoulières, Pelissier, and Bertrand have observed 27 patients with pulmonary parenchymatous localization. The diagnosis is difficult in patients with early parenchymatous lesions or when the disease is associated with the adenopathy of Hodgkin's disease. Large doses of x-rays can slow the course of the disease but the eventual prognosis is poor. The same authors reported on 17 patients with bone lesions in a series of 165 patients with Hodgkin's disease. They confirm the fact that these lesions occur chiefly in the spongy portions, particularly in the spine. Massive doses of x-rays can stop the evolution of the disease. The authors have never observed early skeletal lesions. P. Lehman discussed the future of patients given doses of 3,000 to 3,500 r in 20 to 25 days. Pulmonary lesions are often seen in subjects hypersensitive to x-rays, and it is important to recognize them.

CORRESPONDENCE

PERIODIC HEALTH EXAMINATIONS

To the Editor:—The editorial in the Dec. 19, 1953, issue of *THE JOURNAL* brings into focus vital aspects of the question of periodic health examinations, their validity, and the resistances to their more general application. Several questions are prompted by the discussion in paragraph four of the editorial relating to emphasis on disease rather than on health in educating the public. The interest of the general public on matters of health, bodily function, and good hygiene is illustrated by the success of health museums, exhibits, and lectures. However, these mediums of mass communication have much different implications to the recipients than do close individual attention to and examination of the same public by physicians. The observation of emotional problems in medical patients has convinced me that education in health matters will be successful only as long as the recipient of that information does not feel that he might become the object of an overprotective anxiety on the part of the physician. When a person feels that he is, or may be becoming, the object of the physician's intense concern or overt anxiety, cooperation of that person in health matters drops off sharply. This is true even when the person himself initiates the contact with the physician. The patient fears that the hidden illness that may be found in a periodic health examination may not be subject to definitive therapy. More important, however, he seems acutely aware that his capacity to fulfill obligations (business, financial, and emotional) is being threatened with some degree of curtailment. To avoid this anxiety-provoking possibility for himself, he prefers to avoid medical investigation of hidden asymptomatic illness. The attitude of physicians about their own personal health matters illustrates this point quite well. Certainly a physician is as prone to ignore his physical state as the average lay person and does not submit to annual examinations as commonly as other groups.

In discussing the matter of periodic health examinations of patients with various physicians who have incorporated this into their regular practice, I am left with the impression that rarely does the patient return for these examinations of his own accord. Rather he returns under pressure from his immediate close relatives, from the business firm employing him, or for the reason that he is anxious to fulfill obligations of various kinds to those closest to him. Only a small minority return because of primary anxiety about their own well-being. The success of the Well Baby Clinic is determined by the anxious mother rather than by the free choice of the person under examination. The free choice of an adult about periodic health examinations constitutes a major obstacle to the widespread popular acceptance of it among patients. Understandably, the patient does not wish to enter into an anxiety-provoking situation with the many threats that the discovery of hidden illness implies. As indicated in the editorial, the small minority who constantly seek medical attention because of their own anxiety very frequently resist the ordinary reassurances of the physician. This attitude constitutes an illness in itself. In brief, the patient's anxiety about his obligations and relationships to others mounts sharply when it is faced by frustration. Such frustration is threatened by the physician's search for early or hidden illness. Hence the patient avoids the anxious attention of anyone, including the best-intentioned physician.

Anyone seeking to stress the importance of periodic health examinations may well be forced by the above considerations to exert the pressure on the "patient" indirectly through close relatives or business associates. At the present time, I feel it would be a serious mistake to attempt to put the pressure directly on the patient by any technique. Perhaps in the future an altered attitude toward illness may make these considerations invalid.

JOHN T. FLYNN, M.D.
University Hospitals, Cleveland 6.

HAZARDS OF LIVER EXTRACT AND FOLIC ACID IN LEUKEMIA

To the Editor:—Although our knowledge of the basic factors involved in the leukemic process and the relationship to nucleic acid metabolism is imperfect, there is ample evidence, both experimental and clinical, of the vital role of folic acid and vitamin B₁₂ in normal hematopoiesis. Taking advantage of this fact, of course, has led to the clinical application of antimetabolites and, specifically, folic acid antagonists to therapy of the acute leukemias. Unnatural purines, such as 6-mercapto-purine, are also in use as blocking agents in the chain of nucleic acid synthesis for acute leukemia therapy. It seems irrational, therefore, to administer folic acid or liver to a patient with acute leukemia. The same contraindication to vitamin B₁₂ seems probable, although there is conflicting evidence as to the specific role of this substance in nucleic acid metabolism of the leukocytic series. While this conclusion seems self-evident, there apparently is insufficient appreciation of this fact by the medical profession at large.

I have recently observed instances of rapid worsening in two cases of acute leukemia in adults and apparent conversion of a chronic myelogenous leukemia into an acute phase immediately after ill-advised administration of liver and vitamin B₁₂ in another patient. In all three cases, these hematopoietic agents were given because of the finding of "anemia!" The diagnosis of leukemia was obvious in all three cases by simple observation of a routine peripheral blood smear.

"Shot-gun therapy" is always to be deplored. Usually in "anemias" such empirical administration of drugs is harmless except to the patient's pocketbook, although confusion and obscurity of a specific etiological diagnosis may be produced thereby. In the case of anemia due to acute leukemia, however, the blind administration of powerful hematopoietic drugs may be actually disastrous. It has long been recognized that irradiation is contraindicated in the acute leukemias, and the same contraindication to folic acid and liver should be recognized. It is true that the course of acute leukemia is very capricious and that dramatic changes in peripheral blood cell counts, cell morphology, and symptomatology occur commonly without any form of treatment. Nevertheless, the courses of these three patients were so similar immediately after the administration of liver extract that a cause and effect relationship seems justified.

Although three cases have no statistical validity and the course of events may have been coincidental, there is no way of knowing how often a similar situation may occur. Particularly with increasing recognition of early phases of leukemia, manifested only by unusual anemias, leukopenias, or thrombocytopenia, it seems timely to express this warning and to solicit the opinions and experiences of other members of the profession.

F. W. ELLIS, M.D.

COLLECTION OF BLOOD BY RED CROSS

To the Editor:—I would like to correct the statement that appeared on page 14, of the Jan. 9, 1954, issue of *THE JOURNAL* and that gave the blood collection figures of the Red Cross for the fiscal year ending June 30, 1953. The Red Cross procured a total of 4,121,250 pints of blood, of which 1,791,650 pints were distributed to civilian hospitals and 2,329,600 for defense. Of the blood collected for defense purposes, 383,852 pints were collected by the cooperating blood banks and 1,945,748 pints were collected by Red Cross centers.

DAVID N. W. GRANT, M.D.

MEDICAL MOTION PICTURES

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

Artificial Respiration: 16 mm., black and white, sound, showing time 10 minutes. Produced in 1952 by the United States Coast Guard, Public Information Division. Procurable on loan (service charge \$2.00) from Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

This film consists of scenes specially made on the seashore but concludes with a number of shots made in other environments, to show the details of two methods of artificial respiration, namely, the back pressure arm lift and the back pressure hip lift methods. It would have been well to demonstrate the insertion of a nasal catheter since it was shown in place on two different occasions. The advice to use 5% carbon dioxide with 95% oxygen is not in accord with discoveries of the last three or four years; 100% oxygen is now considered best by the majority of physiologists. In spite of these minor comments, it is hard to imagine a type of audience that would not profit from seeing this film. It can be shown to any audience from cub scouts to medical groups that is interested in the subject. The picture is well organized and the photography is excellent.

Congenital Malformations of the Heart: Part III. Cyanotic Heart Disease: 16 mm., color, sound, showing time 28 minutes. Prepared by Robert F. Rushmer, M.D., University of Washington School of Medicine, Seattle. Sponsored by Dr. and Mrs. Maimon Samuels, Seattle. Produced in 1953 by the Department of Medical Illustration, University of Washington. Procurable on loan (service charge \$3.00) from Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

This film deals with the principles involved in altered physiology of the heart in cases of congenital cyanotic heart disease. It is well illustrated with fluoroscopic and x-ray studies of these conditions in a series of children as well as with a number of animated schematic drawings. The etiology of cyanosis is considered, pathological lesions are demonstrated, and differential diagnosis as well as the principles of surgical therapy are illustrated and discussed. There is fine organization of the material presented. Illustrations, animation, and photography are excellent. The sound track is distinct and well prepared and in one section clearly reproduces the characteristic murmurs of some types of congenital cyanotic heart disease. This film is recommended for general practitioners, pediatricians, and medical students.

The Physiology and Conduct of Normal Labor: 16 mm., black and white, silent, showing time 45 minutes. Produced in 1941 by Joseph B. DeLee, M.D. (deceased), Chicago Lying-In Hospital. Procurable on loan (service charge \$4.00) from Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

The physiology of the first stage is explained and the dilatation of the cervix is demonstrated by animated drawings. The conduct of the first stage with diagnosis of presentation, position, station, etc., is given. Next the mechanism of the second stage is shown on a model. A natural delivery is demonstrated without interference and the same delivery is repeated in slow motion in order to give the lecturer an opportunity to describe the mechanism of labor. The conduct of the third stage is illustrated with models and animated drawings and the film ends by showing the repair of the perineum and the after-care of the baby. Although this film was produced in 1941, the procedures shown are still fundamentally sound and it presents all the mechanisms it is possible to portray. The animation is good and the photography is excellent. It is recommended for county medical societies, medical students, and nurses.

Some Aspects of Accessible Cancer: Part I. Skin: 16 mm., black and white, sound, showing time 29 minutes. Produced in 1951 by the Realist Film Unit, London. Principal advisors: The Royal Cancer Hospital, Westminster Hospital, Middlesex Hospital, and Mt. Vernon Hospital and Radium Institute, and under the general supervision of Sir Stanford Cade, F.R.C.S., Malcolm Donaldson, F.R.C.S., and Dr. G. F. Stebbing. Procurable on loan (service charge \$3.00) from Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

This film concentrates on rodent ulcer and squamous cell carcinoma though other rarer skin cancers are shown. A series of typical cases is exhibited on the screen, and treatment by radiotherapy and by surgery is illustrated. Cosmetic factors and plastic reconstruction are also explained and demonstrated. The importance of early and efficient treatment of these cases is emphasized, and the tragic effects of neglecting apparently trivial lesions is dramatically shown. Great emphasis is laid on the technique of examination of the patient, on metastases, and on the propriety of the use of radiation therapy or surgery or a combination of both. The demonstration of cases before and after treatment is impressive and educational. The film stresses the necessity of early diagnosis. This film is recommended for the general practitioner and also for dermatologists. It is well organized and, although it is not in color, the lesions are very well illustrated.

Some Aspects of Accessible Cancer: Part VI. Rectum: 16 mm., black and white, sound, showing time 24 minutes. Produced in 1951 by the Realist Film Unit, London. Principal advisors: The Royal Cancer Hospital, Westminster Hospital, and St. Marks Hospital, under the general supervision of Sir Stanford Cade, F.R.C.S., Malcolm Donaldson, F.R.C.S., and Dr. G. F. Stebbing. Procurable on loan (service charge \$3.00) from Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

This film points out the importance of rectal examination in all suspicious cases of bleeding from the rectum, followed if necessary by sigmoidoscopy. Surgery is the treatment of choice in most cases, and the British method of performing an abdominoperineal resection is shown, followed by a demonstration of the synchronous combined procedure. The low mortality and good results of early surgery are emphasized, and the successful management of colostomies is illustrated. The film consists of a very clear and concise presentation of the problem of rectal cancer and it is excellent from a teaching standpoint. It is recommended for general practitioners and medical students. This picture is well organized and, although it is not in color, the lesions are very well illustrated.

MOTION PICTURE REVIEW

The Compound Microscope: 16 mm., color, sound, showing time 22 minutes. Produced in 1953 by Sturgis Grant Productions, New York, for and procurable on loan from Film Distribution Service, Bausch & Lomb Optical Co., Rochester 2, N. Y.

The film opens with a review of the types of microscopes in general use today, then demonstrates the construction, basic principles, correct operation, and care of a modern laboratory microscope. The microscope is assembled, unit by unit, with a commentary on the function of each part. Basic optical principles are clearly shown with animated color drawings. To give a clear demonstration of illumination control and focusing, a split frame is used in portions of the film, giving students a view of both the external operation and the microscope field simultaneously. An illustrated 48 page student manual is designed to supplement information contained in the film and aid the student in understanding and using a microscope. Every person who uses a microscope, unless he is already familiar with details, will profit from this picture. There are a great many persons who have been using the microscope every day for years and who are not familiar with the principles of its use; as a result they do not make full use of this complex piece of equipment. The film can be recommended to medical students, students of medical technology, and science students in general. Even experienced pathologists will find a few valuable pointers. The photography and narration are excellent.

BUSINESS PRACTICE

This is the first of a series of articles by these authors on various phases of business practice. According to the authors there are several kinds of accounts, but none represent money in the bank if they only represent figures in books.—ED.

WHAT ARE YOUR ACCOUNTS WORTH?

Chester Porterfield
and

Geoffrey Marks, Seattle

"I made \$60,000 my first two years of practice, but then I went broke!" was the lament of a physician recently seeking management counsel. He had indeed recorded that total of charges, and, in the sense that he had actually done the work they represented, he had earned the money, but, since he did not collect more than a small percentage of it, it did not take long for his capital to evaporate and his creditors to force him into bankruptcy. This may be an extreme example, perhaps, but it is a true one. The obvious lesson, that money on the books does not equal money in the bank, was further demonstrated to this hapless doctor when he attempted to borrow money on his accounts and, at the same time, to contact patients in person about their long overdue bills. Of course his accounts were rejected as collateral, and their lack of value was confirmed by his lack of success at bringing in more than a few token payments and feeble promises. Significantly, the very patients for whom he had done the most and who consequently owed him the most were the least responsive. Not only had their initial appreciation and gratitude evaporated; they were now replaced by resentment and even open antagonism. He gave up the struggle, closed his office, and moved to try his luck elsewhere.

Few solo practitioners are faced so bluntly with our leading question, since most have had to make some acquaintance with the economic facts of life as they began to establish their practices. This may be unfortunate, since moderately good collections and a satisfactory income usually lead them to ignore the fact that their accounts receivable are building up excessively to the detriment of their future success and good relations with their patients. Rather than recognize that the unpaid bill usually results from their own initial mishandling of the patient in one respect or another, most of them will rationalize either that the patient is a charity case or a "dead-beat" or that their secretaries have been negligent. Actually, inept administrative and collection procedures merely compound the doctor's original error. Therefore he overlooks the chance that the patient's eventual resentment and refusal to pay may turn into an attack on his medical proficiency and integrity. The basic collection problem is thus one of public relations rather than one of finances or office management, but that whole question is better deferred for more intensive development in a future article.

ARE ACCOUNTS RECEIVABLE ASSETS?

Usually the first time the man in solo practice has to face an evaluation of his accounts is when he seeks to float a major loan or when he plans to take in a partner and the accounts

are included among the assets to be purchased. The evaluation for bank-loan purposes has a purely memorandum value and must be more properly considered as in the nature of a character reference asset, but, when the purpose is that of establishing purchase value for a new partner, the question can and often does lead to serious rifts and disagreements among the partners. These basically result from the false analogy that accounts receivable are assets and can be assigned a "book value" in the same sense that partly depreciated furniture can be. When considered for purchase evaluation, they represent only potential future income and have no true value until received as such. The degree to which they will be collected will depend largely but not only on the active continuing efforts put out to insure collection, which will be closely related to the continuing level of service and its acceptance by patients, but also on the effectiveness of the pre-existing collection program. Frequently the evaluation is arrived at by a process known as "aging" the accounts. This involves segregating them as to date of the most recent payment or treatment with more or less arbitrary declining percentages of collectability assigned to those groups of increasing age. The extent and consistency of the previous collection efforts by the office and the policy toward turning accounts over to collection agencies give clues as to what percentages may reasonably be assumed, and the progressive ratio of total receipts to total charges for private patients is another helpful indicator.

COLLECTIONS IN A CLOSED PRACTICE

As an indication of what may actually happen, we will cite figures for a solo practice that was closed because the well-established practitioner was entering military service. A better response would be expected here than where a practice is closed either by the physician's death, extended illness, or removal to another city, when the anticipation of future service and the quality of continuing service are eliminated as factors encouraging payment. The physician in the former instance would be returning to his own practice and patients after a limited absence. Current collections had been running at almost 94% of total charges, but the six months after the close of the practice saw just 37% of the accounts on the books collected. However, this discouraging result, doubly so in view of an intensive collection program beginning with announcement letters to all open accounts followed by monthly letters in place of statements to those not meeting current payments, shows a different picture when broken down by categories. For the purpose of analysis, the accounts were classified as active, last treatment within three months or last payment within two; inactive delinquent, no treatment within three months or payment in last two months; active delinquent, some member of the family constantly under treatment but with little or no effort to reduce large balances owing; and active obstetric. The initial distribution and six-month response were as follows:

(a) *Active*.—39% (representing just less than three months' average charges to private patients) were in this class. In the six-month period, 56% were paid, 10% were sent to a collection agency, and the 34% balance were approaching that stage.

(b) *Inactive Delinquent*.—At closing 16.7% of the accounts were in this class and were already receiving collection letters from the office over the doctor's signature. These letters continued, signed by his secretary, and in six months just 21% of them were collected, 11% went to the collector, with 68%

remaining outstanding. This was just over one-fourth of the collections from inactive delinquent accounts for the previous six-month period in the same office and appears to demonstrate the importance of the doctor's continuing presence even to a group that was no longer in active contact with him.

(c) *Active Delinquent*.—These totalled 36% of the accounts and, for a variety of reasons, had been exempted from any form of collection pressure. Letters could not previously be sent because of frequent treatment, and suggestions for direct contact had brought assurances from the doctor that they were mostly good friends, "slow but sure," etc., and that these accounts were no cause for concern. In six months, 23% were collected, 23% sent to a collector, with 54% still outstanding. In addition to the announcement letter and follow-up reminders, the extremely poor response the first three months, contrary to the doctor's anticipation, necessitated special letters from his attorney and the threat of legal action to over three-fourths of this group. Some 60% of the amount collected resulted from this severe and costly approach.

(d) *Active Obstetric*.—Of the total accounts, 8% were in flat fees for obstetric cases not yet delivered on which partial payments were being made. These were pro-rated with the covering obstetrician; those due to deliver within three months, 42%, completed their payments to the closed office. The balance of the accounts were transferred and the percentage of collections is not known.

When, at the end of six months, it was decided that the downward trend of receipts was rendering the program unremunerative and that all accounts would have to be turned over to an agency, 44% of the original total of accounts remained on the books—30% from the active group, 26% from the inactive delinquents, and 44% from the active delinquents. Almost the only certain conclusion that can be drawn is that accounts are not worth what they seem to be worth when something happens. The case cited was chosen as a relatively clearcut example, although it was not one of "final departure," and it must be assumed that accounts taken over by a partnership will fare better. (Unfortunately, in such circumstances the accounts often lose their identity because of continuing services and it is hard to find material for a comparable study.) Our conclusion remains that accounts more than 90 days old are questionable assets, and the wise physician will at all times attempt, through positive and continuing action, to limit his accounts receivable to two or three months' charges.

ACCOUNT VALUATION IN A PARTNERSHIP

The above instance should at least illustrate that "aging" is likely to prove no more satisfactory a method than any other when a determination of value must be made. A method often employed in forming partnerships, and again largely an arbitrary one, is to place a percentage value (usually between 80 and 90%) on prepartnership accounts. Where an accurate record of charges as well as receipts has been kept, a reasonable "purchase value" can usually be set at the actual average percentage of receipts to charges obtained for the previous six month period. This percentage is the figure we shall be referring to as the collection ratio, and we consider it one of the most significant indicators of the health of a practice. We define it as the ratio of net professional cash receipts (excluding other items of professional income such as salaries or retainer fees) to total charges made (before writing off accounts canceled or assigned for collection). Care should be exercised in comparing these ratios with percentages quoted from other sources, since different bases of determination are often used. In practices where good collection procedures have been an integral part of progressive patient relations, the collection

ratio should be maintained at between 95 and 98%; the new partner entering such a practice will in effect be buying a much better assurance of future income than if the previous collection record was as low as the 60 to 70% we have seen in some poorly managed practices. But problems of evaluation may arise even when collection procedures seem quite effective, especially if a partner's retirement share is based on the total of outstanding accounts. For example, in one medium-sized group practice, the collection ratio had been consistently running above 96%, but, over a period of five or six years, the uncollected accounts had almost all remained on the books with none turned over for collection or formally written off at the completion of the business office's own contact efforts. This is usually an excellent way to convince patients that "You don't have to worry about paying your doctor." As a result, the total of accounts had been permitted to increase until they had reached 4.5 times current average monthly charges, an "overage" that in fact exceeded \$100,000.

The first step taken on correction of the situation was segregation of the longest outstanding accounts, particularly those where all contact had lapsed. Those outlawed by operation of the statute of limitations were immediately written off; the others either received special final letters or were immediately turned over for collection, but with little hope of return since current address information was missing in most cases. The second step was to institute a regular program of monthly surveys of all accounts. Letters over the business manager's signature went to the inactive-delinquent group. All active-delinquent accounts were specially signaled for direct contact by whichever doctor next saw a member of that family. As the program continued, additional accounts were recommended for collection assignment or write-off every month. In this way, the accounts total has been brought down to a reasonable level, current income increased to over 100% of current charges, and the doctors are assured that the active accounts on the books represent nearly full value in collectability.

The most significant point demonstrated in our study of this experience was this: In practically all instances where an account had been outstanding for more than a year, letters from the office brought no response whatsoever. When these accounts went to the collection agency, even those who could still be located and contact made ignored all appeals including the final threat of legal action. While no complete correlation of length of time outstanding against response was attempted for accounts under a year old, only 30% of the number between 6 and 12 months acknowledged the letters with payment or commitment; the remaining 70% had to be assigned for collection action and were removed from the active accounts total. The loss of potential income involved is therefore considerable but, even after discounting for the collection fee, will be less than if such final action had not been taken.

COMMENT

In short, the best way to avoid disappointment in evaluating accounts receivable is to keep them current by means of an active collection program in the practice itself. Personal contact and regular reminder letters from the office will take care of the majority of incipient delinquent accounts and will disclose true hardship conditions, which justify writing off the few that legitimately deserve charity. Formal assignment to a collection agency should be reserved for patients who deliberately ignore all reasonable attempts at settlement or who cannot be located by other means. All such accounts should be removed from the active group, at least so far as consideration in the total dollar evaluation is concerned.

- Neuro-Ophthalmology. F. Payne.—p. 644.

Radiation Cataract.—Ham says that isolated cases of radiation cataract appeared among the early x-ray technicians and later among patients who had received radiation therapy to the head. He also mentions the formation of cataracts in physicists who had been exposed to radiation from cyclotrons or to accidental nuclear reactions. Furthermore radiation cataracts were observed in some of the survivors of the atomic explosions at Hiroshima and Nagasaki. The main part of this review is concerned with experimental studies on radiation cataract. In the concluding comment the author says that, from a survey of the human cases, it is apparent that 10 to 20 rep of fast neutrons must be regarded tentatively as a sufficient dose to induce lens opacities that may interfere with eyesight. Additional data are needed to determine the cataractogenic x-ray or gamma ray dose in humans; until such data are forthcoming, it seems wise to consider 500 r of x-rays or gamma rays as potentially dangerous to the human lens. Cytological and biochemical researches on the lens suggest strongly that the lens epithelium may be the initial site of biological injury, leading eventually to radiation cataract. One of the major functions of the lens epithelium may be to provide energy for metabolism in the cortex and nucleus. Inactivation of the enzyme systems in the epithelium after irradiation may be a contributing factor in mitotic inhibition. It is likely that the relative effects of neutrons and x-rays on the generative tissue of the lens epithelium are also similar to the effects in other generative tissues but that, because of the unique structure of the lens, the toleration dose of ionizing radiation is smaller than in other tissues. When bone marrow, for example, is injured by radiation, the damaged cells may be sloughed off and, after various metabolic changes, removed or excreted; eventually, the bone marrow recovers its biological function if the dose of radiation is not overwhelming. The lens, on the other hand, appears to have a "memory" for cellular damage, so that cells that are abnormal but still viable remain within the lens for life because of the lens capsule and eventually collect around the equator or posterior pole, where

they attempt unsuccessfully to differentiate into normal lens fibers. This capacity of the lens to store up damaged cells could account for its susceptibility to chronic doses of radiation. In a sense, it becomes a question of how many damaged cells the lens can tolerate before the clinical manifestation known as radiation cataract interferes with vision.

Arteriosclerotic Aneurysm of Abdominal Aorta.—Of 23 patients with arteriosclerotic aneurysm of the abdominal aorta operated on, 18 had the aneurysm reinforced with nonabsorbable polyvinyl sponges (Ivalon); 4 underwent thromboendarterectomy and fascial wrapping; and resection of the aneurysm of the abdominal aorta and its replacement by grafts of preserved aorta was carried out in 1. Two of the 18 patients died, 1 of renal failure on the 17th postoperative day and the other of massive thrombotic occlusion of the iliac arteries, necessitating a second operation about 10 hours after the first; the patient died 24 hours later. Follow-up studies were done on 15 patients treated by reinforcement of the abdominal aortic aneurysm with polyvinyl sponges for from two and a half months to two years; five patients died as a result of the disease, and a sixth patient, although still alive, suffered from constant, severe, and progressive pain. Thus six patients presented evidence of continuing extension of the aneurysm despite treatment. The remaining nine patients treated by reinforcement are alive and without pain. One of the four patients in whom thromboendarterectomy and wrapping was performed died in the immediate postoperative period. Of the three patients who survived the thromboendarterectomy, two had uncomplicated convalescence. In the third, the first patient in whom thromboendarterectomy was done, arterial insufficiency developed in the left leg in the early postoperative period, necessitating a mid thigh amputation. The patient who was treated by resection of the aneurysm and replacement by an aortic homograft had a satisfactory convalescence. Pulses were normal in both legs at all times. Final evaluation of this procedure will require com-

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

parison of results in a larger series of such cases with results in an untreated control series. Since preparation of this paper, resection of aneurysms and replacement by preserved grafts have been done in four additional patients without death.

Surgical Closure of Atrial Septal Defects.—Twelve patients with septal defects between the ages of 5 and 48 years were treated surgically by one of two methods. 1. For treatment of all defects that lie in the central posterior part of the septum, the method consisted of obtaining closure after digital exploration by drawing the septal edge back to the posterior wall of the auricle with mattress sutures. It was possible to perform the necessary steps by passing a finger into an auricle through the appendage, effectively and thoroughly closing the septal orifice, withdrawing the finger, and suturing the auricular appendage, all in less than 10 minutes. The technique is simple and gives little disturbance to the heart. 2. For lesions that may be very high, very low, or very far forward and for all of the openings that are large, a rubber "well" can be attached to the opened auricle, forming a pool of blood through which the fingers can be passed into the auricular chamber and allowing by tactile direction with the fingers repair of the septal opening by direct suture or by the onlay of a polyethylene sheet that is made to cover the opening. Such a sheet was placed in 3 of the 12 patients. It remained for more than a year without any untoward effect. Five of the 12 patients died; two deaths occurred at the termination of operation or later in the same day. They were related to errors in defect closure or to insufficient replacement of blood loss during operation. Two deaths occurred a week after operation when clinical and roentgenologic features indicated that blood was damming up in the left auricle and pulmonary bed. Digitalization, reduction of blood volume, and limitation of salt ingestion might prevent such disasters in the future. The fifth fatality occurred in a 38-year-old man who was known to have a very high vascular resistance and a beginning reversal of flow through the septal opening (arterial oxygen saturation of 88%). The authors now believe that such a situation is a contraindication to surgery. There were seven survivors. In four of these the septum was repaired by direct suture, and in the three others the opening was closed by the onlay of a polyethylene sheet. The postoperative course was most gratifying in these seven patients. The activity and force of the heart beats were unquestionably reduced. Those who before had right-sided heart failure had now lost all evidence of this. The capacity for physical activity was greatly augmented. Physiological studies demonstrated pronounced reduction in the work of the right ventricle. Small interauricular shunts can be tolerated by the human heart through a long life and, hence, do not require any surgical relief; large interauricular shunts in which the pulmonary blood flow is twice or more that of the peripheral flow should be subjected to surgical closure of the septal opening.

2-Hydroxystilbamidine in Blastomycosis.—Two Negro men aged 40 and 29 years, respectively, and a 4-year-old Negro girl with proved systemic North American blastomycosis and an 84-year-old white man with the cutaneous type of the disease

were treated with 2-hydroxystilbamidine di-isethionate, containing 54% 2-hydroxystilbamidine. Initially the three adult patients were given 0.11 gm. of the drug intravenously in 20 cc. of 5% dextrose in isotonic sodium chloride solution over a period of 20 minutes. No toxic effects were observed. This dose was repeated every other day and then daily, and in the two Negro patients the daily dose was increased to 0.225 gm. One of the Negro men received three courses of six weeks' to two months' duration, with a total dose of 19.6 gm. of the drug. The other Negro man received a total dose of 8.1 gm. over a period of 52 days. The white man received a total dose of 4.5 gm. in the course of six weeks. The Negro girl had multiple chronic skin lesions with draining sinuses involving the scalp, face, neck, thorax, scapulae, abdomen, hip, and all extremities, associated with pyrexia of five and a half months' duration, and was in a dying state when admitted to the hospital. In view of the promising results of chlortetracycline (Aureomycin) therapy in previous cases of systemic North American blastomycosis administration of this antibiotic was immediately started using 250 mg. every six hours. Forty-eight hours later 2-hydroxystilbamidine di-isethionate therapy was also instituted employing 28 mg. in 10 cc. of 5% dextrose intravenously each day. After four days the dose was increased to 56 mg. every 24 hours, and 11 days later the dose was further increased to 75 mg. daily for eight weeks. Because of pronounced vascular sclerosis, treatment was discontinued for a week and then resumed with 75 mg. of the drug given intramuscularly in 2 cc. of 5% dextrose in isotonic sodium chloride solution containing 20 mg. of procaine hydrochloride. Treatment was given daily for one week. Thereafter 2-hydroxystilbamidine was discontinued as the patient's condition had greatly improved and the supply of the drug was exhausted. Administration of chlortetracycline was continued with an increased dose of 1.2 gm. daily. While the follow-up period in the four patients treated with 2-hydroxystilbamidine was short, objective and subjective improvement in all the patients was most encouraging, at times even dramatic. Prolonged observation will be required for definite evaluation of this method of treatment. Extensive clinical and laboratory studies revealed no definite evidence of toxicity resulting from the prolonged and extensive administration of 2-hydroxystilbamidine. In none of the patients did trigeminal neuropathy develop. In vitro studies established a definite inhibitory effect of 2-hydroxystilbamidine on four strains of *Blastomyces dermatitidis*; 2-hydroxystilbamidine may be slightly more effective than stilbamidine in the mold phase of this organism. In critical cases of systemic North American blastomycosis, chlortetracycline may advantageously be combined with 2-hydroxystilbamidine in treatment.

C-Reactive Protein in Rheumatic Fever.—Serial determinations of C-reactive protein in the serums of 62 patients with rheumatic fever were carried out during various stages of the disease. C-reactive protein was present in moderate to large amounts in the serums of 34 of the 35 patients studied during a period of frank rheumatic activity. Of 11 patients studied during the stage of low-grade rheumatic activity after a frank attack of rheumatic fever, 10 had C-reactive protein in their serums. In another group of 11 patients, there was doubt as to whether the acute rheumatic process had subsided because of persistence of an increased erythrocyte sedimentation rate. C-reactive protein was demonstrated in the serums of 6 of these patients and treatment was instituted. In the remaining five who had negative results from the C-reactive protein precipitin test, the erythrocyte sedimentation rate was restored to normal levels spontaneously. These patients subsequently had an uneventful recovery. Of the 62 patients, 5 had so-called pure chorea unassociated with any other clinical or laboratory finding suggestive of rheumatic activity. All five had negative results from the C-reactive protein precipitin test. These observations confirmed those of Anderson and McCarty, in that the presence of C-reactive protein in the blood of a rheumatic patient is an extremely sensitive and reliable indicator of rheumatic activity if other unrelated pathological

processes can be excluded. Certain isolated rheumatic manifestations, however, may be present without causing the appearance of C-reactive protein in the patient's blood. These include chorea, erythema marginatum, subcutaneous nodules, and Aschoff bodies in the auricular myocardium. The behavior of the C-reactive protein in the blood of 58 of the 62 patients with rheumatic fever also was studied during and after antirheumatic therapy; 23 patients were given cortisone, 4 corticotropin (ACTH), 26 acetylsalicylic acid (aspirin), 3 aminopyrine, and 2 sodium gentisate. The disappearance of C-reactive protein from the blood was a good prognostic sign for the termination of a rheumatic attack but did not preclude the possibility of a future polycyclic recurrence. Persistence of C-reactive protein in the patient's blood during treatment with the antirheumatic agents indicated inadequate suppression of the inflammatory process. Six illustrative cases are reported.

Sanitation of Crushed Ice.—Anyone who has watched the dispensing of crushed ice in chilled drinks knows how frequently fingers touch the ice, whether or not a scoop is used. The usual result is seeding with coliform organisms. Ice to be put in an iced drink or brought in contact with food should conform bacteriologically to the Public Health Service standards for potable water. The authors describe studies on crushed ice dispensed in food serving units at Harvard University. Evidence was obtained that most of the undesirable bacteria were introduced in the dispensing of the crushed ice. A comparatively simple technique was developed for chlorinating the crushed ice previous to dispensing. A stock solution is prepared by adding to a clean gallon (4 liters) jug 25 ml. of 4% hypo-

chlorite solution, or 20 ml. of 5.25% solution. This jug is filled with tap water and kept tightly closed and under refrigeration. This solution will keep about a month. The disinfecting solution is prepared by adding one ounce (30 gm.) of stock solution to each gallon of tap water and mix. This solution is poured into the container of crushed ice until the latter is practically covered. The ice is dispensed directly from the container. Two years' experience with this chlorination procedure in some 15 food serving units has shown that the ice now dispensed meets reasonable sanitary standards and that there is no noticeable impairment of flavor in ice water and iced drinks made with the chlorinated ice.

Bronchial Tuberculosis in Resected Lungs.—Six hundred two surgical specimens resected from patients with pulmonary tuberculosis were studied with particular reference to bronchial pathology. In only 10% of the specimens were the bronchi normal. The incidence of different types of bronchial involvement was: chronic bronchitis, 29%; tuberculous bronchitis, 20%; bronchiectasis without endobronchial tuberculosis, 21%; and bronchiectasis with endobronchial tuberculosis, 20%. Some degree of endobronchial tuberculosis was present in 40%, and ectatic bronchi in 42%, of the total specimens. Of those specimens with bronchiectasis, 49% had associated tuberculous endobronchial lesions. Hilal bronchial stenosis was present in 38 specimens. Thirty-three of 302 specimens had microscopic evidence of hilal endobronchial tuberculosis. Tuberculous endobronchial foci were more frequently associated with "cellular" and open cavitary parenchymal foci. They were also commoner in specimens from those patients who had moderate or far advanced disease, who had the disease for less than three years' known duration, who had received no streptomycin and p-aminosalicylic acid or less than four months therapy with it, and who had lobectomies or pneumonectomies. Bronchiectasis was more frequently associated with fibrocaseous parenchymal foci and moderate to marked interstitial pulmonary fibrosis. It was also commoner in specimens from patients who had moderate or far advanced disease, disease of

more than three years' known duration, and lobectomies or pneumonectomies. The duration of streptomycin-*p*-aminosalicylic acid therapy had no influence on the incidence of ectatic bronchi. Noncavitary specimens from patients who never had roentgenographic signs of cavitation and who received nine or more months of therapy with streptomycin and *p*-aminosalicylic acid still had a 27% incidence of endobronchial tuberculosis. Thirty-seven per cent of the specimens from patients who had normal bronchoscopic examinations actually showed endobronchial lesions. This discrepancy is not astonishing as similar findings have been reported by Buckles and associates. The technical difficulties probably responsible for it are discussed; it is probable that careful pathological examination of the lung may uncover lesser degrees of bronchiectasis than are visible on the bronchogram. Emphasis should be placed on the necessity of utilizing both techniques in order to obtain the closest possible correlation.

Nonspecific Tuberculin Sensitivity.—More than 22,000 young women who entered 76 schools of nursing throughout the United States between 1943 and 1949 were tuberculin tested with two doses (0.0001 mg. and 0.005 mg.) of purified protein derivative (tuberculin), or PPD, and answered questionnaires on history of contact with tuberculosis and on all places of residence since birth. Analysis of the material shows that the frequency of those reacting to the first dose increases with increasing degree of contact with tuberculosis: from approximately 10% positive in the group reporting no contact to 20% in those with intermediate and 40% in those reporting close contact. Increased exposure simply affects the frequency, not the intensity, of sensitivity to the first dose. In contrast, the frequency of those reacting to the second dose, expressed as a percentage of those negative to the first dose test, is entirely independent of degree of contact, but closely related to place of residence. Nearly 70% of the permanent residents of the southeastern states were positive to the second dose, compared with less than 30% of those in the rest of the country, regardless of their classification as to contact with the disease. In addition, 40% of those from the southeast had skin reactions exceeding 9 mm. in diameter, compared with 12% from the north and west. The results of this study and of others previously published are consistent with the hypothesis that tuberculin sensitivity in human beings can no longer be regarded as being derived from a single source. Most reactions elicited by a low dose intradermal test (approximately 0.0001 mg. of PPD) undoubtedly indicate specific infection with virulent tubercle bacilli, spread by personal contact. Low degrees of sensitivity brought out only by large doses (1 mg. of old tuberculin or 0.005 mg. of PPD, for example) apparently represent infection by a different organism with a different mode of transmission. The latter (unidentified) organism must be antigenically related to the tubercle bacillus, highly prevalent in certain geographic areas, and apparently nonpathogenic for human beings.

Chronic Sodium Chloride Toxicity.—The chronic effects of sodium chloride in the diet of mammals were studied in a long-term experiment made on male albino rats. Purified rations, containing from 0.01% to 9.8% of sodium chloride, and water were fed at will from the age of five weeks. Water consumption was related directly to the amount of salt in the diet. A low sodium diet depressed the appetite, but diets high in sodium chloride did not. Edema developed in 18% of the rats placed on the diets that contained from 7 to 9.8% of sodium chloride. Important pathological lesions were observed in the kidneys and to a lesser extent in various other tissues of rats consuming these high levels of sodium chloride. Sustained arterial hypertension was observed in the rats eating high levels of sodium chloride after nine months of the dietary regimen. A linear relationship existed between the sodium chloride concentration in the diet and the systolic blood pressure. The parallel to human hypertension is obvious, but none of the findings in rats can be directly applied to man without extensive further study to evaluate the sensitivity of man to salt.

Current Status of Chemotherapy of Tuberculosis.—From a number of different cooperative studies, carefully conducted with controls assigned by random, it was possible to establish the superiority of certain variables in the chemotherapy of tuberculosis in the last few years. A combination of 1 gm. of streptomycin administered twice a week with 12 gm. daily of *p*-aminosalicylic acid, for periods up to one year resulted in a high degree of therapeutic efficacy and relatively little toxicity and drug resistance. Isoniazid in doses of 300 mg. daily in combination with streptomycin or with *p*-aminosalicylic acid also appears to be effective, although its recent advent has not yet permitted as complete evaluation as with streptomycin and *p*-aminosalicylic acid. Results of chemotherapy in general are less satisfactory when there has been prior chemotherapy than in patients receiving original treatment, and this is in part related to drug resistance. When partial streptomycin resistance has developed as the result of prior streptomycin therapy, some benefit is still to be derived from continued streptomycin therapy, unless that resistance is as high as complete resistance to 100 mcg. per ml. The availability of isoniazid, as a second effective drug, improves the clinical outlook in these patients. When drug resistance to both streptomycin and isoniazid has developed, viomycin in doses of 2 to 3 gm. twice a week was found to be an effective antituberculous agent, though probably of more limited efficacy than streptomycin or isoniazid. It is desirable always to give combined therapy with more than one anti-tuberculosis drug, and *p*-aminosalicylic acid appears to be the preferred drug to be given with either streptomycin or isoniazid. When intolerance to *p*-aminosalicylic acid exists, oxytetracycline (Terramycin) may be employed as substitute. Effective chemotherapy in tuberculosis results in resolution of the reversible components of the disease in a high percentage of cases, leaving residual fibrosis and necrosis. The best clinical management of such residual tuberculous disease, in association with prolonged effective chemotherapy, was not determined with precision.

Perforated Peptic Ulcer.—During the five year period 1948 to 1952 inclusive, 942 patients were admitted to the King County Hospital in Seattle, Wash., for treatment of peptic ulceration. There were 672 patients with duodenal ulcer, 241 with gastric ulcer, and 29 with marginal ulcer. Perforation had occurred in 136 (13.2%) of the patients with peptic ulceration, and 32 of these patients, or nearly a fourth of those with perforation, died. The patients were observed in a charity hospital. Many were of a relatively advanced age or were derelicts from the skid road. All but 18 of the 136 patients were men. Perforation of a gastric ulcer proved a much more serious condition than that of a duodenal ulcer (mortality in surgical cases 16.6% and 2.7%, respectively). The authors feel that the most important single factor in reducing this high mortality is early institution of therapy. They used operative closure of the perforation, or subtotal gastrectomy in selected patients, as the treatment of choice. Their results in patients treated by a conservative regimen including gastric suction were not good. This may, in large part, be due to the type of patient in whom this form of treatment was employed. The management of the acutely intoxicated chronic alcoholic patient and the chronically malnourished alcoholic patient with gastroduodenal perforation is a trying problem and one that contributes significantly to the high mortality associated with this condition. Four of the six deaths in the surgically treated patients were directly associated with severe alcoholism, and two of them died in delirium tremens. In the patients treated by initial simple closure or by conservative means, recurrence or persistence of ulceration is frequent in the type of patient seen in a charity hospital. The authors feel that elective subtotal gastrectomy within eight weeks after perforation is advisable in selected cases.

Vascular Dynamics in Controlled Hypotension.—The investigation described by Morris and associates is concerned primarily with measurements of cerebral blood flow and cerebral oxygen consumption in surgical patients with marked hypotension induced by hexamethonium. The aim was to determine, if possible, the safe blood pressure ranges that may be employed in surgery under controlled hypotension. Additional studies included differential renal function and blood volume measure-

ments. Cerebral hemodynamic studies were done on five normotensive and three mildly hypertensive surgical patients. Hexamethonium chloride was administered by continuous intravenous infusion (500 mg. of hexamethonium per 1,000 cc. of 5% dextrose in water) to the unanesthetized, horizontally supine patient. Anesthesia was omitted in order that disturbances in cerebral function could be immediately recognized, thus increasing the safety factor in these initial studies. Continuous mean blood pressure recordings were made from a mercury manometer connected to a needle inserted in the femoral artery. A significant decrease in cerebral blood flow followed marked depression in the mean blood pressure in spite of a decrease in cerebral vascular resistance. Cerebral oxygen consumption was only slightly decreased due to a more complete extraction of oxygen from the blood flowing through the brain. Renal function studies were carried out on 12 surgical patients. It was found that, initially, glomerular filtration rate and renal plasma flow were both depressed. However, after two to three hours of maintained hypotension, renal plasma flow returned to control levels whereas glomerular filtration rate remained depressed. Hexamethonium-induced hypotension decreased urine formation. Blood volume estimations were made in 16 surgical patients before induction of hypotension and again after induction. Blood volume was slightly increased because predominately of an increase in plasma volume. There appears to be little danger of cerebral or renal anoxia in the supine patient with a mean blood pressure as low as 55 mm. Hg when employing hexamethonium-induced controlled hypotension.

Esophageal Varices in Portal Cirrhosis.—According to Palmer, it is a common observation that patients with the severest cirrhosis do not necessarily have the largest or most extensive esophageal varices. This raises important clinical questions such as: How valid an estimation of the degree of portal hypertension can be derived from inspection of esophageal varices? Do enlarging varices indicate increasing portal pressure? Studies were made on 25 patients with esophageal varices secondary to portal cirrhosis. These patients were examined serially by esophagoscopy, and measurements were made of varix diameter, extent of esophageal involvement, and portal venous pressure. Two conclusions were reached. 1. There was not close correlation between changes in portal pressure and changes in varix severity among individual patients; however, varices did not become smaller if the pressure increased or larger if the pressure fell. 2. There was no correlation between a certain portal pressure level and the severity of varices among different patients. The author concludes that enlarging varices are not necessarily an indication of rising portal pressure, that the degree of diminution in variceal severity following portal decompression does not necessarily indicate the degree of decompression achieved, and that portal pressure cannot be estimated from varix severity.

Blindness from Retrolent Fibroplasia.—According to Krause blindness in the premature infant has become a major problem during the past 15 years. Retrolent fibroplasia is its most frequent cause. Factors that have been ruled out as playing the etiological role in retrolent fibroplasia are listed, but answers still remain to be supplied as to why this disease was practically unknown before 1937 and why it is more prevalent in certain hospitals. Changes in pediatric management seem to be the most likely explanation. High concentrations and long-continued use of oxygen have been mentioned as a possible cause of retrolent fibroplasia, but many infants with and without added oxygen to their environment have developed retrolent fibroplasia. The common opinion of those who have investigated this factor is that oxygen concentration is not a primary cause but may be indirectly associated with the disease. The fact that in some hospitals premature infants fed only human milk never have retrolent fibroplasia is cited as another significant factor. Believing that the disease may be related to edema and vascular stasis caused by disturbance or poorly controlled water and electrolyte metabolism in the premature infant, salt in the daily food intake was restricted so that it approached the concentration and amount of salt in human milk. Only one infant annually developed retrolent fibroplasia after that. With this clew the investigation on this problem was continued. There is no specific treatment for retrolent fibroplasia. In the early stages of venous dilatation, retinal edema, and serous exudation the disease may retrogress. If the retina is slightly or partly detached for a short time, it may reattach with little damage to the eye, but marked detachments lead to a loss of sight.

Pilomotor Response to Intradermally Injected Nicotine in Diagnosis of Leprosy.—Arnold points out that the pilomotor and sudomotor (gooseflesh and sweating) reactions to intradermal injections of highly diluted solutions of acetylcholine and nicotine salts have been shown to be of the nature of axone reflex responses that are abolished by denervation at the postganglionic level. Loss of the sweat response to pilocarpine or acetylcholine in leprosy has been used by many

workers as an aid in the diagnosis of that disease. It has been found useful in the study of small or nonanesthetic, hypopigmented, nonbacillate macules, and in the differentiation of the sensory dissociation of leprosy from that due to syringomyelia. Rothman suggested that the pilomotor response to intradermally injected nicotine, which is much stronger than that produced by acetylcholine or its derivatives, might be as useful as the sweat test for this purpose. Arnold describes his experiences with the intradermal injections of 1:100,000 and 1:50,000 aqueous solutions of nicotine picrate in several patients with leprosy. The pilomotor (and sudomotor) response to intradermally injected nicotine picrate in 1:100,000 solution appears to be regularly abolished by leprosy involvement of the skin, both within and near demonstrably involved areas. It is not invariably observed even in normal skin, however, and is often absent on the face. The stability of nicotine picrate in aqueous solution and the fact that only this solution and a syringe and needle are required for the test constitute distinct advantages of this test over the tests for sweat secretion. The pilomotor test shares with the sweat tests the advantage over the older histamine test of being as easy to read in highly pigmented skins as in light ones. The author concludes that a normal pilomotor (gooseflesh) response to an intradermal injection of 1:100,000 nicotine picrate solution strongly suggests that the lesion within which it occurs is not due to leprosy. Failure of the response to occur is of uncertain significance.

Nisentil as an Obstetric Analgesic.—This report is concerned with the use of Nisentil (1,3-dimethyl-4-phenyl-4-propionoxy-piperidine) hydrochloride, dl-alpha form, in the delivery of 44 primiparas and 56 multiparas at the hospital of the Woman's Medical College in Philadelphia. Labor was present in all cases as evidenced by effacement of the cervix with an average cervical dilatation of 4 cm. and regularly recurring uterine contractions. The drug was administered subcutaneously in doses of 40 to 60 mg. and repeated as needed for optimum analgesia. No adjuvant drug was used. Observations were made regarding adequacy of analgesia, onset and duration of action, side-effects in the mother, and evidence of fetal respiratory depression. The results obtained in these women were compared with those obtained in 75 women who received only meperidine (Demerol) and in 25 who received meperidine in combination with scopolamine. It was found that in doses of 40 to 60 mg. Nisentil hydrochloride is a satisfactory, flexible obstetric analgesic. Good to excellent results were obtained in 92 of the 100 women. There were no untoward side-effects in the mother or in the infant when the drug was given within 30 minutes of delivery. It shortens the course of labor, and its outstanding advantage is the rapidity with which maximum analgesic action is obtained.

Drugs Against Airsickness.—Chinn and associates cite previous reports on the superiority of scopolamine hydrobromide (1 mg.) over promethazine hydrochloride (Phenergan) in the prevention of seasickness. Both compounds have also been reported of value in airsickness prophylaxis, although the scopolamine dosage employed in these cases was 0.65 mg. rather than 1 mg. In further testing these drugs with respect to airsickness, the long-acting antihistamine Postafene (*p*-chlorobenzhydryl *m*-methyl benzylpiperazine dihydrochloride) was included, because of preliminary reports indicating an extremely long protective period and a paucity of side-effects. It was found that 1 mg. of scopolamine affords greater protection against airsickness than 25 mg. of Postafene or 25 mg. of promethazine, both of which, however, significantly lower the incidence of airsickness. Postafene protects for at least 24 hours after oral administration. The side-effects produced by these drugs were slight, the most significant being an increased incidence of dry mouth after scopolamine.

Hexamethonium and Renal Function in Hypertension.—After a single dose of hexamethonium administered parenterally to patients with hypertension, the glomerular filtration rate and renal plasma flow are immediately depressed. Within one hour, however, renal hemodynamic readjustment occurs and both functions return to or toward control values, although the

arterial blood pressure remains depressed for two to six hours. The present study was designed to evaluate the effects of prolonged reduction of blood pressure in hypertensive patients, with and without renal damage, during the therapeutic oral administration of hexamethonium. Patients with hypertension were studied by measurements of glomerular filtration rate (inulin clearance), renal plasma flow (*p*-aminohippurate clearance), and maximum tubular excretory capacity (Tm_{PAH}). Studies were made on renal hemodynamics of patients in the supine position and during ambulation. In the supine position, there was a reduction in blood pressure after hexamethonium without a reduction in renal plasma flow, glomerular filtration rate, or tubular excretory capacity. These observations indicate that the renal vessels in patients with hypertension are quite capable of dilating. In the ambulatory state before hexamethonium, there was a depression of glomerular filtration, renal plasma flow, and Tm_{PAH} due to vasoconstriction. After hexamethonium therapy, the ambulatory state was accompanied by a further drop in blood pressure and a reduction in renal functions quite similar to those observed in the untreated patient, but the changes were often more marked. Ambulation after the administration of hexamethonium is accompanied by a decrease in the excretion of water, sodium, and potassium. This may be due to neurogenic impulses as suggested by the depression during ambulation alone without a drop in blood pressure. Hexamethonium when used orally in the continued treatment of hypertension appears to be acceptable since none of the changes described resulted in any significant alteration of their clinical status in terms of impaired excretion of nitrogenous substances or in the retention of sodium and water. Reactivity in the recumbent position seems to compensate for the depressed function during ambulation.

The Fundus Oculi of the Premature Infant and Retrolental Fibroplasia.—Follow-up studies on 117 prematurely born infants discharged from the Jefferson Davis Hospital prior to 1950 disclosed none with residual lesions of retrolental fibroplasia. The first appearance of this disease coincided with the establishment of a modern, well-equipped premature unit and improvement in survival rate. Since April, 1950, periodic examinations of the fundi of 320 premature infants have been made. Most of these infants weighed less than 1,700 gm. at birth. The ophthalmoscopic examinations disclosed that very small premature babies are born with an immature fundus that passes through a transitional stage before reaching the mature fundus similar to that of the full-term infant. After maturation, the eye may remain normal or may progress on to show the early changes of retrolental fibroplasia. The early changes in turn may reverse spontaneously or may progress to varying degrees of visual impairment. Of the 320 infants examined, 86 had retrolental fibroplasia, 38 of whom developed massive retinal edema with detached retinas and malignant hemorrhages. There was a significantly increased incidence of retrolental fibroplasia in the white and boy infants, which may possibly be related to a greater immaturity and poorer survival rate. The smallest infants and those with the most immature fundi at birth are the ones in whom severe retrolental fibroplasia with its resulting blindness is most likely to develop. Evidence is presented to show that the small premature infant

and those infants with severe retrolental fibroplasia have a high and fluctuating myopia, which may remain as a residual lesion. The author also comments on the parts played by (1) relaxed tone of blood vessel walls, (2) increased arterial tension, and (3) decreased peripheral resistance in the pathogenesis of the early stages of retrolental fibroplasia. It could not be demonstrated, within the limits of this study, that they were of significance. With regard to the possible role of excess or deficiency of oxygen, the author points out that the fetus in utero lives in an atmosphere of lowered oxygen tension. During exposure of the infant to 40 to 60% oxygen atmospheres in incubators, maturation of the eye is carried on in the presence of a higher oxygen tension than would be present in utero. Gyllenstein recently demonstrated that an atmosphere excessive in oxygen does have a deleterious effect on the eyes of newborn mice. Rapid oxygen withdrawal may also be of importance. From the observations presented, the author concludes that retrolental fibroplasia appears to result from an as yet unknown factor or series of unknown factors affecting an immature eye that is passing through a period of critical differentiation and maturation.

Gamma Globulin in Measles Encephalitis.—The first 590 cases of measles encephalitis and encephalomyelitis reported in the literature are reviewed. These encephalitic forms occur in about 0.3% of patients with measles, and the mortality rate in these forms is about 15%. The following theories have been propounded to explain the involvement of the central nervous system: (1) the measles virus acquires neurotropic characteristics; (2) some latent virus is activated by the primary disease; (3) toxins in the central nervous system produce the encephalitis; and (4) the encephalitis is an allergic or anaphylactic reaction to the measles virus. Odessky and his associates say that many authors are of the opinion that there is no definite evidence to support any of these theories, and they suggest the following additional hypotheses. 1. Because of a previously poor nutritional state, fever, and general debility from the attack of measles, the hematoencephalic barrier becomes more permeable, resulting in the invasion of the central nervous system by the virus. 2. The patient is not able to produce sufficient antibodies, that is, he does not have the faculty to acquire immunity as rapidly as do 99.7% of patients with measles. 3. There are rare persons who cannot establish acquired immunity because of an inability to produce antibodies. 4. There is a possibility that the antibodies, which are probably protein substances, have an affinity for a protein molecule and are destroyed more rapidly than they are formed because of the fever. In connection with this last point, the authors comment on the use of gamma globulin, which was used in the majority of the 41 patients with measles encephalitis and encephalomyelitis that are presented in this paper. Fifteen of these received 20 cc. or more of gamma globulin early in the acute phase (a total dosage of from 0.43 to 1.1 cc. per pound of body weight); 12 patients received from 4 to 16 cc. of gamma globulin early in the acute phase (a total dosage of from 0.07 to 0.30 cc. per pound of body weight); and 14 patients were not treated with gamma globulin in the acute phase. The results were better in the first than in the other two groups. This group had a greater recovery rate, less numerous and less severe sequelae, a normal temperature by the third day, a shorter hospital residence, no fatalities, and no secondary pneumonia. These patients made remarkable recoveries in view of the extensive nervous system involvement. Four patients received gamma globulin alone in the acute phase and made the same rapid recovery as those given antibiotics or sulfonamide drugs in addition. There were no local or systemic reactions to therapeutic doses of gamma globulin. The recommended dose is 1 cc. per pound of body weight, given intramuscularly in divided doses, over a 36 to 48 hour period, as soon as the signs and symptoms of central nervous system involvement are manifest. The patients should receive in addition to gamma globulin adequate fluid and electrolytes, oxygen, antipyretic therapy, suction, balanced feedings, sedatives as needed, magnesium sulfate, antibiotics, and sulfonamide drugs. The authors suggest that gamma globulin can be used in complications of the central nervous system from viral diseases other than measles.

Heart Disease from Viewpoint of Patient.—Simpson emphasizes that in spite of all research and progress in the advancement of the knowledge of the treatment of cardiovascular disease, complete success is not possible when all attention is directed primarily to the disease itself. The problem is not one of merely keeping the patient alive but should include efforts to make him live as comfortably and usefully as is possible. To do this we must not forget to consider heart disease from the viewpoint of the patient. We must be able to anticipate his fears and anxieties. When we order him placed in an oxygen tent, we should tell him why. When we say he will need so many weeks of bed rest and inactivity, he should be told why. When we insist that he lose weight or change his habits or working conditions, he is entitled to know and understand the reasons.

Nor Epinephrine in Waterhouse-Friderichsen Syndrome.—A fatal case of fulminating meningococcal bacteremia with Waterhouse-Friderichsen syndrome is described in a 53-year-old woman. Control of infection, shock, and adrenal insufficiency

were the three essential objectives in the treatment of the patient. For the control of infection an initial dose of 6 gm. of sulfadiazine sodium was given intravenously in 1,000 cc. of 5% dextrose in isotonic sodium chloride solution, and subsequent dosage of this drug was guided by blood level determinations at intervals of four to six hours, aiming at a range of 15 to 20 mg. per 100 cc. of blood. One million units of aqueous penicillin was given every two hours intramuscularly after an initial dose of 500,000 units given intravenously. The infection was brought under control, since cultures of heart blood and cerebrospinal fluid at autopsy grew no organism. Shock and adrenal insufficiency remained the major problems and were responsible for the fatal outcome despite treatment with aqueous adrenal cortical extract given intravenously and additional cortisone given intramuscularly. Arterenol (nor-epinephrine) was administered in the intravenous fluids in a concentration of 4 mg. per liter of fluid. A prompt pressor response was obtained from this; the blood pressure rose from an unobtainable level to 100/60 mm. Hg almost immediately and was maintained at a satisfactory level after an optimal speed of the drip had been attained. In the course of the first 24 hours of hospitalization a total of 5,300 cc. of fluid was given including dextrose, sodium chloride, and plasma. Despite this, only 180 cc. of urine was excreted, and consequently the volume of fluid administered was thereafter kept at a minimum and arterenol had to be administered in a much higher concentration than usual if its pressor effect was to be maintained; 24 mg. (24 cc.) of arterenol thus was introduced into each 1,000 cc. of fluid, instead of the usual 4 mg. per liter. A total of 1,600 cc. of fluid was given during the second 24 hour period. The urinary output remained scanty. No signs of venospasm or phlebitis along the polyethylene catheter, through which the infusion was given, were observed. Prompt elevation of the blood pressure was obtained each time after the normal speed of the drip was assumed following interruptions of flow by the administration of other medications and procedures. Such immediate and continuous easily controllable effect has obvious advantages over other agents previously used. It is hoped that other workers may explore the use of arterenol in order to clarify its place in treatment.

Escherichia Coli Meningitis.—In a 33-year-old man with concurrent pyelonephritis, Escherichia coli bacteremia, and meningitis, combined antibiotic treatment was started with intravenous administration of sulfadiazine, streptomycin, and large doses of penicillin while awaiting the results of spinal fluid and blood cultures. The following morning these cultures were positive for E. coli; penicillin was then discontinued and replaced with oxytetracycline (Terramycin) given intravenously. For the first four hospital days, the patient who had been a heavy drinker for several years remained confused and lapsed periodically into delirium tremens. The temperature returned to normal by the end of the fourth day. The spinal fluid cleared gradually, showing 103 cells on the fifth day and 14 cells on the 12th day. All blood and spinal fluid cultures were negative after treatment was started. The patient was discharged free of infection after 27 days of hospitalization. Data are presented of 35 cases of E. coli meningitis in adults, children, and infants collected from the literature since 1941. Fourteen of the 35 patients died, a mortality rate of 40%. Ten of the 14 deaths occurred in patients with penetrating war wounds of the head and spine complicated by meningitis and treated with sulfadiazine and penicillin in addition to any necessary surgery.

Acute Pancreatitis.—Of 134 patients with acute pancreatitis admitted to the Massachusetts General Hospital between 1946 and 1951, 16 died during the acute attack, a mortality rate of 12%. Compared with previous experience, this improved mortality reflects the use of antibiotics, as well as other advances in diagnosis and treatment. Of the 118 patients who survived the acute attack, 42 had no definitive treatment. Ten of these 42 patients could not be traced or had short follow-up periods that were inadequate for evaluation; 4 patients died of causes unrelated to the gastrointestinal tract; 32 patients were followed up for 12 to 60 months; and 22 of these had no similar attacks and were classed as having obtained good results. In four patients with vague upper abdominal complaints, the results were considered fair, and in 6 with recurrent symptoms the results were classified as poor. Thirteen of the 42 patients had had more than five previous attacks; 6 of these had no further attacks; 2 had vague symptoms; and 5 continued to have similar attacks. Thus, in the untreated patients the poorer results seem to correlate roughly with a greater number of preceding attacks; results in these patients with many previous attacks were quite unsatisfactory when no corrective surgery was attempted. This contrasted sharply with the results in the 76 patients treated after the acute attack. Of these, cholecystectomy and choledochostomy were performed at varying intervals in 59, miscellaneous surgical procedures were carried out in 13 and choledochostomy in 4 who had had a previous cholecystectomy. Fifty-one of the 59 patients were followed for 12 to 72 months; results were good in 47, fair in 2, and poor in 2. Of 35 patients who had had more than five previous attacks, 28 were followed up for one year or more, results being considered good in 26 and fair in 2. Thus patients treated by cholecystectomy and choledochostomy did surprisingly well. The two so treated who

continued to have serious attacks of pancreatitis were the only patients in whom patency of the ampulla was never established. Cholecystectomy and choledochostomy are most effective in patients in whom recurrent attacks of pancreatitis have not produced permanent changes such as calcification in the pancreas. An alert attitude is urged in the detection of attacks of acute pancreatitis and appropriate surgery on the biliary tree after the acute attack has subsided. This program seems to offer the best approach to the prevention of the serious late manifestations of recurrent pancreatitis that are so difficult to manage.

Aschoff Bodies in Left Atrial Appendage.—Aschoff lesions are manifestations of tissue reaction to injury. Convincing evidence has been presented that they are specific for rheumatic fever. The authors studied the hearts of 40 patients who died of severe fulminating rheumatic fever. In 29 of the 40 hearts, one or more Aschoff lesions were found in the atrial appendages; 25 (85%) also had the lesions in the routine necropsy sections. The incidence of these lesions in the left atrial appendage thus correlated closely with that of similar lesions elsewhere in the heart. These findings were compared with those in surgical specimens removed by biopsy during mitral commissurotomy in 40 patients with mitral stenosis who showed no recognizable clinical or laboratory signs of recent rheumatic activity. Aschoff lesions and other microscopic changes in the atrial appendages were identical in both groups. No similar lesions were observed in patients without rheumatic fever or in nine patients with rheumatic heart disease who survived beyond the fifth decade and whose hearts were available for comparison. The conclusion seems inescapable that the presence of Aschoff bodies in the atrial appendage of the surgical specimens indicates some degree of rheumatic activity. Recent observations during the postoperative phase lend clinical support to this concept.

Legg-Perthes' Disease.—Siewers says that although the etiology of osteochondritis deformans coxae juvenilis is unknown, the pathogenesis is well understood. It is a circulatory impairment of the head and neck of the femur, resulting in capsular soft tissue congestion and later in aseptic necrosis and degeneration of the femoral head. In varying lengths of time the avascular head is replaced with granulation tissue, and osteogenesis follows, with reconstruction of the bony components. This cycle may take from three to four years to be completed and can be followed by means of serial roentgenograms. The first symptom is usually a limp, neither severe nor disabling but more noticeable with fatigue or increased physical stress. Pain may or may not be present; if it is, the site is more frequently in the knee than the hip. Clinical examination usually shows muscle spasm about the hip. Treatment should be begun as soon as the disease is suspected and discontinued only when the roentgen and clinical findings do not substantiate the diagnosis. The main object of treatment is to prevent weight bearing. Traction with bed rest may be used in the early stages. After regeneration has begun, the use of crutches or an ischial weight-bearing brace until the femoral head is recalcified is the most generally accepted program of treatment.

Polyneuritis Caused by Isoniazid (Isonicotinic Acid Hydrazide).

—Höök had the opportunity to examine a number of patients in whom treatment with isoniazid (isonicotinic acid hydrazide) gave rise to various neurological disorders. In this report he is concerned with one form of these neurological disorders, the peripheral neuropathic variety. The histories of seven patients are presented, all except one of whom were given isoniazid in combination with either *p*-aminosalicylic acid or dihydrostreptomycin. There was nothing to indicate that this combination therapy favored the development of the polyneuritic symptoms. Polyneuritis developed on an average of two months after the commencement of treatment with isoniazid. Clinical experience and experimental investigation have demonstrated that in certain forms of polyneuritis, as in poliomyelitis, the greater the degree of physical activity in the initial stages the greater is the likelihood of nerve injury. Such a relationship was not observed in the present series. Neither did there seem to be any relationship between the patient's general condition and the appearance of polyneuritic symptoms. This neuropathy or polyneuritis is characterized by predominantly sensory symptoms usually symmetrically distributed in the distal parts of the extremities, as a rule in the lower limbs. The principal features are impairment of postural sensibility and appreciation of vibration, hyperalgesia in the soles of the feet, and, in some cases, paresis of the distal muscles. The electromyogram shows a typical peripheral nerve lesion. In the majority of the cases observed, the symptoms were mild and regressed fairly rapidly after discontinuance of the therapy. Paresthesias appear to be the first symptoms of polyneuritis. The risk of severer damage to the peripheral nerves makes the appearance of these symptoms the signal for close observation.

Tobacco and Coronary Vessels.—The electrocardiographic manifestations following the inhalation of tobacco smoke were studied in normal dogs and in dogs with ligated coronary arteries. The dogs were anesthetized by intravenous injection of pentobarbital (Nembutal) or chloralose; a tracheal cannula of the type used for closed-circuit anesthesia was inserted; and inhalation of the smoke was then secured by placing a cigarette in a holder at the free end of the cannula. The cigarette was repeatedly withdrawn after the animal had completed an inspiration and was replaced after one or two normal respirations until one or two cigarettes were consumed, thus reproducing the conditions found in habitual smokers. Disturbances of rhythm were purposely ignored in evaluating the results; only those changes directly attributable to the effect of the smoke on the coronary vessels were taken into consideration. Electrocardiographic changes consisted of alterations in the shape and direction of the T-waves and prolongation of the ST intervals. They occurred with comparable frequency in both the normal dogs and those with coronary ligatures, but were not constant

in either. Similar results were obtained in tests on men with and without coronary disease, indicating that individual susceptibility to tobacco smoke may occur in both man and dogs, conditioned, apparently, by the receptive and reactive state of the nervous system.

Cerebral Pause During Clamping of Aorta Under Hibernation.

—The effect on cerebral activity produced by clamping the aorta of rabbits subjected to artificial hibernation varies with the duration of the clamping. The electroencephalogram of a rabbit subjected to hibernation at a temperature of 32 C resembles that characteristic of deep sleep with slow delta waves of great amplitude, separated occasionally by waves that are slightly more rapid but never so frequent as those found in the waking subject. Clamping of the aorta produces an immediate change in the tracing: within 10 seconds, the rapid waves disappear, very slow waves persist for another 4 seconds, and then, 14 seconds after the application of the clamp, there is an almost complete cessation of all electrical activity that lasts for 12 seconds. Absolute silence follows. Removal of the clamp after a cerebral pause of 1½ minutes is followed 14 seconds later by the resumption of cerebral activity similar to that seen initially. These changes indicate that the circulatory arrest produced by the clamping results in apparent death of the brain at the end of 14 seconds and that normal cerebral activity is restored when the circulation is reestablished. Repetition of the experiment in the same rabbit a few moments later again produced a cerebral pause at the end of 14 seconds; this time, however, the clamp was left in place for 3 minutes. Electrical activity was not resumed until 3 minutes after the clamp had been removed, and when it did reappear it was entirely different in character. These experiments were repeated with the animals at temperatures of 25 and 20 C, and in each case the cerebral pause was followed by renewed activity. At these low temperatures, however, the electroencephalographic rhythm both before and after clamping differed from that found in normal sleep. The cerebral pause, showing failure of ventricular systole, is a danger signal, and when it appears in the electroencephalograms immediate steps should be taken to reestablish the circulation before the cerebral changes become irreversible, especially if the electrocardiograms show a concurrent cessation of cardiac activity. These findings, which have great practical value for the management of artificial hibernation in general, are particularly important when cardiovascular operations are to be undertaken.

Clinical Aspects and Pathogenesis of "Malignant" Synoviomas.

—Ebbinghaus presents the histories of three patients with synoviomas who were observed at his clinic in recent years. The first patient was a woman, aged 30, in whom a tumor had developed on the left ankle joint in the course of two years, causing few symptoms. The tumor was removed, and operation revealed that it originated from the tendon sheath of the peroneus longus. Histological studies disclosed a synovioma. Two years have elapsed since operation, and there has been no local recurrence or metastases. The second patient, a woman 75 years old, had observed for two months the development of a tumor on the right side of the abdomen. This tumor originated from the fascia of the obliquus externus abdominis. Despite radical removal, a recurrence the size of a fist developed in the course of 10 weeks. After two more weeks, multiple pulmonary metastases were demonstrable. The patient died within six months. This course proved the malignancy of the tumor. In the third patient, a man, aged 36, a new tumor developed within four years after the removal of

the primary tumor. The removal of this recurrence was followed by a second one within eight weeks. The leg was amputated, but four months later a pulmonary metastasis was removed. Additional metastases were observed in the arm. The disease was fatal within six years of the development of the primary tumor. The author points out that synoviomias were first described by von Langenbeck in 1865 and that the best recent review is that by Lauche of Frankfurt. This author examined a number of specimens that other investigators designated as adamantinomas of the extremities, but by histological studies Lauche was able to identify them as synoviomias. The lesion has also been designated as synovioplastic sarcoma. The diagnosis of malignant synoviomias can be established only by histological studies. These reveal, in addition to portions resembling spindle cell sarcomas, cysts and clefts containing synovial tissue and around these dense spindle cell casings. These tumors originate most frequently from the bursas of the knee joint, but they are also observed on articular capsules and on tendon sheaths. Malignant synoviomias do not infiltrate their surroundings, but on the basis of their clinical behavior they must be regarded as malignant, because they produce distant metastases and also local recurrences. Whenever a tumor develops on a tendon sheath, a bursa, an articular capsule, or in fascia, malignant synovioma should be suspected and total extirpation should be resorted to at once. Because of the danger of local recurrences, the patient must be kept under close observation.

Are Sunglasses Dangerous?—Hoffmann points out that some advertisements for sunglasses assert that some of the cheaper types of glasses are dangerous, because they permit the penetration of harmful, invisible light into the eye, and they distort the picture and the colors. Investigations and general experience, however, have proved that daylight at low altitudes is harmless and that, therefore, there is no need to protect the eye against it. The author shows that the other criticism is also excessive and one-sided and that there is no reason to be concerned about harmful effects of cheap sunglasses.

Age and Work in Heavy Industry.—Richardson comments on the tremendous and steadily increasing burden represented by retirement pensions and on the fact that an extension of working life beyond the present conventional retiring age would both reduce national expenditure and increase national income. The study here reported was designed to explore the answers to questions relevant to the relation between age and heavy work. Investigations were made in two foundries and a coal mine in which 489 men aged 50 years and over were interviewed. Within the limits imposed by the fact that older persons at work are highly selected, it is shown that the proportion of men on heavy work declined from the age of 50, and with this move off heavy work there was frequently a reduction in skill. Illness or injury was associated with two-thirds of the changes to lighter work. These and other events acted as "trigger factors." The need is stressed for some reduction in work tempo as age increases, and the view is expressed that such reduction should not be at the expense of skill. The problem of the relation of age and work appears some years earlier than pensionable age. The similarity between the trends with age in unemployment, retirement, and changes to lighter work is discussed.

Multiple Metaphyseal Fractures in Small Children.—The occurrence of a generalized bone disease is described in six children, all with onset in the first two years of life. The condition was characterized by multiple metaphyseal fracture-like defects and also by fractures of a more usual type. In each child, the two most striking clinical features were the absence of a history of adequate trauma to account for the widespread lesions and the slight degree of pain and general disturbance produced. The multiplicity of metaphyseal defects and fractures was only evident on roentgenologic examination; most of the abnormalities were undetected clinically. The fractures of more usual type occurred in both flat and tubular bones. The ribs were the commonest site, but the clavicle, femur, tibia, and spine were also involved. Union occurred normally. The multiple metaphyseal defects constituted the most typical radiological feature. They were present at the ends of several of the long bones. They showed as translucent zones, "cutting off a corner" of the bone end. Often it could be seen that a separated fragment was a crescentic portion of the periphery of the metaphysis, sometimes slightly displaced. The defects sometimes disappeared without residual abnormality and reappeared over a period of several months; at other times considerable subperiosteal and soft tissue calcification followed; then healing led to residual cortical thickening and irregularity of contour at the ends of the bone. The reaction around many of the defects indicated that these were of the nature of fractures. The appearances sometimes suggested the possibility that the translucent zones constituted lines of weakness through which there occurred slight fracture separations, with accompanying formation of hematoma. The cause of the syndrome is not known.

Occupational Lung Damage in Ship Repairers.—Of 31 men between the ages of 41 and 73 years, calling themselves by the abbreviated misleading term of boilermakers, but carrying out the repair of ships as riveters, holders-up, rivet heaters, burners, platers, and caulkers, with clinical signs such as cough, stained sputum, dyspnea, and chest pain, 24 showed definite roentgenologic changes in their lungs and 7 did not. In dislodging and burning ship plates and rivets, dust and fumes rising from various materials with which the plates are lined were inhaled by the repairers who had to work in confined spaces. Roofing felt and bitumastic, a hard asphaltic compound, with which the ship plates were lined, were found to include 56% of total silica and 30% of free silica. In addition there was the dust, consisting mainly of iron compounds, created by chipping scale from plates and rivets. The following roentgenologic lesions were noted: (1) increased lung striations only; (2) more pronounced lung reticulation combined with nodulation; (3) pronounced irregular fibrosis without any other apparent lesions; (4) a combination of reticulation, irregular fibrosis, and nodules of varying size; and (5) emphysema. These lesions were or were not accompanied by significant clinical signs or symptoms or incapacity. Until pathological evidence is available in such cases, one must refer to these lesions as lung damage, but not as pneumoconiosis or silicosis. It should be noted, however, that analysis of the various dusts inhaled by these men revealed the presence of both free silica and iron compounds. Of the seven men without definite roentgenologic changes, some had few clinical signs or symptoms, while others had severe symptoms, predominantly dyspnea. In

the two men of this latter group who died, post mortem revealed extensive emphysema and slight pneumoconiosis. As the men were exposed to such a variety of fumes and dusts during their work, only experimental work can be expected to elucidate the responsible factors.

ACTH and Isoniazid in Tuberculous Meningitis.—In an attempt to prevent the formation of the thick basal exudate always present in fatal cases of tuberculous meningitis and to control the development of tuberculous endarteritis, it was decided to give corticotropin (ACTH) intramuscularly or subcutaneously and isoniazid orally, instead of streptomycin intrathecally. Streptomycin given intramuscularly and *p*-aminosalicylic acid (PAS) given orally to delay development of resistant strains of tubercle bacilli were added to the program after it had been tested. This work was started with children at King George V Hospital in Durban, Union of South Africa, in March, 1952, and has proved so successful that the use of streptomycin given intrathecally, as done formerly at that hospital, has been abandoned. Comparative results of the two methods in two groups of 31 patients each are presented in detail. The mortality rate has been significantly lowered. Administration of the combination of corticotropin and isoniazid is simple, and the elimination of the necessity of daily lumbar puncture is considered a great advance. The cerebrospinal fluid appears to return to normal more quickly in children receiving the new treatment than in the patients treated with streptomycin, i. e., one to four months. Complications of the treatment included moon face, edema, one fatal case of pyogenic meningitis and one case of acute otitis media, and mental disturbances due to isoniazid in one adult. There were no cases of deafness and no clinical or radiological evidence of spread of pulmonary tuberculosis while corticotropin was being administered.

Clinical Trials of Influenza Vaccine.—Small-scale trials in the winter of 1951-1952 of vaccines prepared from certain selected virus strains chosen as being representative of the influenza A viruses recovered during the epidemic of influenza in 1950-1951 allowed assessment by serologic methods of the comparative value as antigens of these vaccines. Large-scale controlled field trials of an influenza A vaccine were carried out in 128 centers of Britain in the winter of 1952-1953. The trial vaccine contained equal proportions of a threefold concentration of

F.M.1 strain originally recovered in 1947 in the United States and of the egg-adapted Liverpool 1951 strain, adsorbed on aluminum phosphate. The control vaccine was a bacterial anti-influenza vaccine of low potency. Subsidiary trials were carried out in villages in the Hebrides and in the Vauxhall motor works at Luton. The vaccines were given by deep subcutaneous injection in the left upper arm between Nov. 26 and Dec. 12, 1952. It was hoped that this timing would permit the development of immunization before the expected outbreak of influenza. Of 12,710 volunteers who acted as participants in the main trial, 6,340 received the trial vaccine and 6,370 the control vaccine. There was an attack rate of clinical influenza in 192 (3%) of the volunteers in the trial vaccine group and in 309 (4.9%) of the volunteers in the control vaccine group. This is equivalent to a 40% reduction in influenza in the former group as compared with the control group. Other acute respiratory infections occurred equally often in vaccinated and control groups. The vaccines used were essentially similar to those employed in previous British and American trials, but differed in their low content of nonspecific protein. Aluminum-phosphate-adsorbed vaccines were used, because a low rate of both local and general reactions could be anticipated with this type of preparation. Reactions occurring in the inoculated persons were if anything slightly less severe among those who had been given the trial vaccine than among those given the control vaccine. With both vaccines women suffered more than men. The fact is stressed that the clinical workers and those who recorded the illnesses during the follow-up had no knowledge of the particular type of vaccine received by a volunteer. No outbreaks of influenza developed in the Hebrides; therefore, no results were forthcoming in this subsidiary trial. The trial at Luton, of which the main object was to gain experience of special methods of ensuring accurate diagnosis, will be reported separately.

Streptomycin With and Without Isoniazid in Tuberculous Meningitis.—The results obtained in 27 children with tuberculous meningitis who were treated with streptomycin from January, 1951, to May, 1952, were compared with those obtained in 18 children of the same age with the same disease who were treated with streptomycin and isoniazid from May, 1952, to December, 1952. Streptomycin therapy was instituted in the first group of children within 10 days after the onset of the symptoms, the combined therapy in the second group 10 to 30 days after their onset. Streptomycin was given parenterally in doses of 25 mg. and intrathecally in doses of 2 mg. per kilogram of body weight every day; isoniazid was given orally in doses of 10 mg. and intrathecally in doses of 1.5 mg. per kilogram of body weight every day. Comparison was based on the improvement of the spinal fluid. This occurred in the children who improved between the third and sixth months of therapy with no marked difference between those of the first and second group. The beneficial changes occurred sooner in the children who received the combined therapy. Only 37% of the first group recovered compared with 83% of the second group. There is, however, the possibility that late regressions may still occur in the children of the second group because of the shorter follow-up period. It is not possible to state whether the good results in the children of the second group were due to the combination of the two drugs or to the fact that isoniazid was given intrathecally. Since the drug was tolerated well, it is suggested that this route of administration be employed more widely because there is always a local bacteriostatic action. Combined streptomycin and isoniazid therapy is advocated for tuberculous meningitis.

Chemotherapy of Polycythemia Vera.—Cytostatic agents, namely, nitrogen mustard (N-Lost), ethyl urethane, and triethylene melamine were given to nine men and six women between the ages of 31 and 64 with benign panmyelosis (polycythemia vera) of 2 to 10 years' duration. Some of the 15 patients had already received previous, more or less effective, treatment with venesections and roentgen irradiation. Severe headache and disturbances of blood perfusion were the main complaints. Death resulted from myocardial infarction in a 52-year-old man whose polycythemia had been compensated by triethylene melamine. Bone marrow and blood cell counts were restored to normal by ambulatory treatment without complications in the other 14 patients in whom prolonged remissions of five months to three years were produced. A 64-year-old man, with polycythemia vera of seven years' duration, received a total dose of 932 gm. of ethyl urethane in the course of three years and in addition 200 mg. of triethylene melamine in the course of the last six months; the patient is in good general condition and the blood cell count revealed 100% hemoglobin, 4,800,000 erythrocytes, 8,600 leukocytes, 150,000 thrombocytes per cubic millimeter, and 8 per thousand reticulocytes. A 49-year-old woman received 153 mg. of triethylene melamine in the course of three months, with a resulting remission of 18 months' duration without any further treatment. In a 54-year-old man, a remission of 30 months' duration was produced with 270 gm. of ethyl urethane and 12 mg. of nitrogen mustard. Several patients obtained satisfactory results with ambulatory intermittent, so-called "long-time therapy" with triethylene melamine in small doses up to 10 mg. in the course of four weeks; the dose of the drug was determined by the number of reticulocytes per cubic millimeter of blood. In one patient, absorption of orally administered tablets of triethylene melamine was unsatisfactory; prompt remission resulted after intravenous administration of 50 mg. of triethylene melamine. Lately, a triethylene melamine preparation, in capsules that are soluble in the small intestine, was given a trial; absorption of these capsules proved to be better than that of the tablets, and, therefore, only half of the tablet dose was required. In an addendum, the authors state that three additional patients with polycythemia vera were effectively treated with triethylene melamine administered intravenously.

Clinical Examinations of Patients Undergoing Balneological Sulfur-Iodine Treatment.—Radioiodine uptake tests, measurements of blood pressure and of viscosity of the blood, blood cell counts, measurements of basal metabolic rate, and electrodermatograms were made in 62 patients undergoing balneological sulfur-iodine treatment in a Bavarian spa and in 5 control persons. All these examinations were made on a fasting stomach before balneological treatment was started and after a balneological course of three to four weeks. This balneological course consisted of 10 to 15 baths or drinking a half a glass of sulfur-iodine water daily and inhalation of iodine-containing brine. The radioiodine uptake tests were made with a Geiger-Müller counter after oral administration of 75 mcg. of I^{131} . Results demonstrated that the quantitative behavior in the absorption of iodine differs considerably with the various methods of application. Inhibitory effect and serum iodine level seem to be closely related. A daily average absorption of at least 4 mg. of iodine can be counted on with treatment by drinking iodine-containing water, and daily absorption of 300 mcg. of iodine could be demonstrated in those treated by baths. The absorption of iodine on inhalation of iodine-containing brine proved to be very slight with the aerosol apparatus in use. These quantitative differences deserve consideration concerning the therapeutic use of iodine in patients

with arteriosclerosis and goiter. Results of blood cell counts, measurements of blood pressure and basal metabolic rate, and electrodermatograms suggested a tendency of abnormal values to be restored to normal; these changes may be ascribed to an unspecific effect of the balneological treatment. Patients who complained of general restlessness and tension after the termination of the balneological course presented in the electrodermatogram high values that corresponded to a tonus condition due to stimulation received through the sympathetic nervous system. This suggests prolonged stimulation by the balneological course, and after-treatment is recommended for these patients. The viscosity of the blood seemed to show a tendency to a drop of values that had been high at the start of the balneological treatment.

Streptomycin in Streptomycin-Resistant Patients After Isoniazid Therapy.—Results of in vitro studies at the Istituto Forlanini in Rome had indicated that streptomycin-resistant strains of tubercle bacilli treated with isoniazid lost a great part of their resistance to the antibiotic. The authors tested the validity of these results in 20 patients hospitalized at the Chieti sanatorium with advanced pulmonary tuberculosis and in very poor general condition. Streptomycin had been given to all until it had to be discontinued because resistance to it developed. Isoniazid therapy was then instituted and continued for about two months. After this, streptomycin was given again in doses of 1 gm. daily to 10 patients. The second group of 10 patients received 1 gm. of streptomycin with 4 mg. of isoniazid per kilogram of body weight. The drug, which was administered for one month, was well tolerated by all the patients, except one in whom it had to be discontinued. There was no significant difference in the findings of the two groups. The roentgenograms did not change, and, despite an improved erythrocyte sedimentation rate in 13 patients, the pulmonary condition remained almost unchanged. The temperature was not influenced, and, although the sputum was diminished in some cases, its positivity for the tubercle bacillus was not modified. These results confirmed indirectly the findings of the in vitro tests in that streptomycin resistance in the patients had been influenced by the isoniazid therapy so that almost all of them tolerated well the administration of streptomycin. However, even though the antibiotic was well tolerated, the results of this second course of therapy were so poor that they did not justify the resumption of streptomycin therapy in streptomycin-resistant patients after they have been treated with isoniazid.

Isoniazid (Isonicotinic Acid Hydrazide) and *p*-Aminosalicylic Acid in Treatment of Pulmonary Tuberculosis.—Breathnach calls attention to the property of either *p*-aminosalicylic acid or streptomycin to prevent the fall in sensitivity of *Mycobacterium tuberculosis* to isoniazid. He also shows that Middlebrook's recommendation of never using an antituberculous compound alone is now universally recognized. He feels that the combined use of isoniazid and *p*-aminosalicylic acid is justified in the following emergencies: (1) in patients whose organisms are streptomycin-resistant; (2) in patients who have received a course of streptomycin (30-50 gm.) with another drug, but who still require some form of therapy other than, or

in conjunction with, a temporary collapse procedure to assist bed rest; and (3) in patients exhibiting allergy to streptomycin. However, since patients fulfilling these criteria are few, the author decided to try the combination of isoniazid and *p*-aminosalicylic acid in cases of acute progressive bilateral pulmonary tuberculosis, believed to be of fairly recent origin and in whom cavitation was not a predominant feature, who were unsuitable for collapse therapy, and of the age group 20 to 40. Both preparations were administered orally for three months. Isoniazid was given in an amount of 6 mg. per kilogram of body weight daily in divided doses and *p*-aminosalicylic acid in daily amounts of 600 mg. per kilogram of body weight (in five divided doses). No incompatibility, physical, chemical, or pharmacological, was observed. Bed rest was continued for three months after the cessation of chemotherapy. The results indicated that this regimen has definite therapeutic value. The response to chemotherapy in this trial is evidence of a synergy that safeguards bacillary drug sensitivity. Combined chemotherapy is, therefore, a justifiable alternative when an antibiotic assault on the tubercle bacillus is desirable but contraindicated.

Treatment of Hemolytic Disease of the Newborn.—The trials described were planned at a London meeting at which 17 centers were represented. There was uncertainty about the merits of different methods of treatment of hemolytic disease of the newborn. It was hoped at first that exchange transfusion could be compared with simple transfusion and premature induction of labor with spontaneous delivery at term, selection of treatment for each case being made by a system of random numbers. However, only a few were willing to follow this plan. Some centers wanted to use exchange and simple transfusions alternately and to pursue a fixed policy with regard to time of delivery; others agreed to use premature induction of labor and spontaneous delivery alternately and then to give either exchange transfusion to all infants or simple transfusion to all infants. Women included in the trials were those whose serum was found to contain Rh antibodies, the examination having been not less than 30 days before the expected day of delivery. The analysis of the results of premature induction of labor versus spontaneous delivery suggested that it is unlikely that premature induction of labor increases the chance of survival and that, on the contrary, such a practice may diminish the survival rate. No attempt was made to select cases in which premature induction of labor might have been specially indicated. Nevertheless, since the severity of the disease varies strikingly in successive infants born to the same mother and since the severity of the disease cannot be reliably predicted before birth, it is difficult to see how cases could be specially selected for premature induction, even if it could be shown to be beneficial in severe cases. Unless some new evidence of the value of premature induction of labor in selected cases is obtained, the safest course is to abandon this treatment. Further evidence was produced to support the previous observation

that in hemolytic disease of the newborn the chance of survival is closely related to the hemoglobin concentration of the cord blood, but the policy of withholding treatment from all infants whose cord hemoglobin concentration exceeds about 15 gm. per 100 ml. is seen to be unsatisfactory. Without treatment, the incidence of kernicterus in such infants is about 7% if they are mature and about 16% if they are immature. Most of these infants would probably develop normally if treated by exchange transfusion. If premature induction of labor is avoided, the number of infants born prematurely will be small, and it is feasible to treat all such infants by exchange transfusion, irrespective of their cord hemoglobin concentration. Previous conclusions about the superiority of exchange transfusion over simple transfusion are reinforced; there were not only more survivors among infants treated by exchange transfusion but the incidence of cerebral damage among the survivors was low.

Radiotherapy in Dupuytren's Contracture.—Dupuytren's contracture, if left untreated, slowly progresses with an increasing flexion deformity of one or more fingers and accompanying increasing functional disability. Of the various treatments that have been recommended, surgery is widely regarded as the method of choice. Treatment by ionizing radiations has received little attention, except in Sweden and Germany, and the rationale of treating a condition in which the main emphasis has been on contracture following fibrosis is not at first apparent. Radiotherapy has been long used in the treatment of keloid and hypertrophic scars, both alone and in conjunction with surgery. Further, the effect of irradiation on the fibroblasts shows that their mitotic cycle can be interrupted. As a result of irradiating the whole palm, it should be possible to interrupt the cycle of events producing further contracture. The results of treating 25 cases of Dupuytren's contracture with radium are reviewed. Gamma radiation alone was used. In the early stages, before contracture has occurred, a planar mold is made and the area to be irradiated is mapped out on the mold. A treating distance of 1 or 1.5 cm. is used. In the stages when contracture has occurred and a planar mold can no longer be applied, a grip cylinder is made of a radius of 1 or 1.5 cm. The total dose of 3,000 r to the skin is given in fractional doses of eight hours a day for eight days. In no case did the patient have difficulty in wearing or in retaining the appliance. Apart from dryness and occasional slight erythema, no skin reaction was observed. Subjective improvement, including softening of the nodules, lessening of paresthesia, and increase in finger movement, were evident within the first four weeks. Objective improvement, gauged by increase in movement, began on an average within 1.7 months and became maximal by 6 months. The condition was never made worse by irradiation, but it remained the same in one-fourth of the patients, whereas three-fourths showed improvement. In the early stages, it may be as successful as radical surgery. In more advanced cases, irradiation may be followed by radical surgery; complete excision of the aponeurosis can be undertaken without fear of recurrence.

Mitral Stenosis with Cor Pulmonale.—There is a group of patients with mitral stenosis in whom symptoms and signs of cor pulmonale develop unexpectedly. The syndrome may appear in the course of any of the clinical forms of mitral stenosis and at any time during the evolution of the disease, with alternating periods of aggravation and improvement. Onset of the syndrome is marked by aggravation of the disorders of respiration, dyspnea, cough, hemoptysis, cyanosis, and repeated bouts of spasmodic asthmiform bronchitis. There are clinical symptoms and roentgen and electrocardiographic signs of overload of the right ventricle, rapid establishment of right circulatory stasis, and rapidly progressive diminution of physical strength. Functional disorders include great diminution of the respiratory reserve, a reduced minute volume, and increase of the arteriovenous flow, of the resistance of the pulmonary arterioles, of the capillary pressure, of the gradient of arteriocapillary pressure, and of the work of the right ventricle. The treatment consists of mitral valvuloclasia and valvulotomy, which should be made early in the course of the syndrome. The macroscopic anatomic aspects of the syndrome include tight mitral stenosis, marked hypertrophy of the walls of the right ventricle, signs of tricuspid insufficiency, and dilatation of the pulmonary artery and its main branches. The lung shows alternating zones of emphysema and pneumonitis. The microscopic aspects include hyperplasia of the intima of the small arterioles, elastosis of the large arteries, lesions of rheumatic arteritis in various stages, and parenchymal and interstitial ischemic or rheumatic lesions.

Antibiotics in Heart Disease.—The authors report clinical and bacteriological cure of bacterial endocarditis in 38 out of 63 patients who received penicillin alone or in association with streptomycin and in rare cases with some other antibiotics. Penicillin was given intramuscularly in doses of 300,000 units at intervals of three hours for a period of four or five weeks. Streptomycin was given in doses of 0.5 gm. every 12 hours. They also report results in approximately 100 patients with cardioaortic syphilis. It was observed that the Kahn and Wassermann reactions, which were resistant to arsenicals, became permanently negative after daily doses of 500,000 to 1,000,000 units of penicillin for two or four weeks. Negative reactions became positive in one or two weeks from daily doses of 500,000 units of penicillin, and then they again became negative as a result of the treatment. Penicillin failed in advanced cardioaortic syphilis. From a review of the literature the authors believe that the incidence and severity of rheumatic fever has diminished since the introduction of antibiotics. From observations on two large groups of patients, they conclude that recurrences of rheumatic fever and occurrence of suppurative streptococcal infection of the upper respiratory tract complicating rheumatic fever are less frequent in patients who have had antibiotics.

- Diet in Pulmonary Tuberculosis. A. Turletti Tola.—p. 934.

Genetic Problem of Tuberculosis.—A review of the literature was made to evaluate the factors that intervene in the causation of tuberculosis. The conclusions reached by the many authors who studied this matter extensively are thus summarized: (1) there is a hereditary predisposition to the disease that is based on the person's constitution; (2) this predisposition is a specific hereditary character; and (3) the genotype factors do

not have great importance for the manifestation of the disease. As for the mode of hereditary transmission, some authors, after studying numerous genealogical trees, formulated the theory of a recessive monomeric hereditary transmission while others that of a probable recessive polymeric heredity of tuberculosis. If this hereditary predisposition to tuberculosis is accepted, those measures that will prevent the transmission of the disease not only from the standpoint of contact but also from that of the diffusion of the genetic factors of tuberculosis should be enforced.

Secondary Tuberculosis of Hilus of Lung.—Secondary tuberculosis of the hilus of the lung (involvement of the entire hilus) becomes manifest as an acute febrile episode. Although easily confused with influenza and other infectious diseases, it can be recognized in that the mild cough, which is very frequent, is accompanied only by insignificant pulmonary physical findings. The most characteristic diagnostic feature is a roentgenogram indicating involvement of the hilus with an exudative process that diffuses to all the complex structures that form the hilus from an adenopathy that is already in an advanced phase of cicatricial regression. Secondary tuberculosis of the hilus of the lung was at first thought to be an entirely new phenomenon related to an abnormal allergic situation produced in the Italian population by the difficulties of the war. But since more and more cases have been and are being identified (probably because of a greater use of roentgenography), the hypothesis was advanced that this condition represents a transitional phase from the primary to the secondary localization of the tuberculous infection. On the basis of recent tomographic studies, it was asserted that the main characteristic of the condition is, in addition to the primary complex, a parenchymal process that is simultaneous to a hilar adenopathy from which it derives. The authors cite three patients in whom there was an unexplained elevated temperature with dry cough, mild sweating, and mild impairment of the general condition. The diagnosis of secondary tuberculosis of the hilus of the lung was made after the roentgenograms had revealed the characteristic picture of involvement of the left hilus. This disease seems to occur rather frequently during the transition to secondary pulmonary tuberculosis.

Corticotropin in Hyperplasia of Thymus.—Corticotropin was given to 21 children, 1 to 17 months of age, with disturbances of the respiratory, circulatory, digestive, and nervous systems attributable to hyperplasia of the thymus. The doses at first small (3.5 mg. daily) were gradually increased until some infants were given as much as 20 mg. daily. Most of them received two five day courses of treatment with a two week treatment-free interval between. The clinical signs disappeared rapidly or gradually in most and never reappeared. The size of the thymus was reduced in many and became normal in seven. However, roentgenograms taken after discontinuation of the treatment revealed that the thymus was again hypertrophic in several children and sometimes to a greater degree than before treatment was instituted. The congenital laryngeal stridor present in a few children was not influenced by the hormone, and this seems to prove the theory of its mechanical origin in a deformation of the trachea that persists for some time. Eosinopenia was present in most of the children after administration of the hormone, and the number of eosinophils rose to above the initial values after the therapy was discontinued. Although corticotropin does reduce the volume of an hypertrophic thymus and makes the clinical signs disappear, the author fears that this hormone may constitute a danger to the adrenals that in these children are already hypoplastic. The stimulus that the hormone exerts on them may alter the functional

activity of the adrenal cortex. Anatomic alterations of the adrenals were observed in one child who died of diphtheria during the treatment. Not only hypoplasia of the organ was present but there was also a decrease of the lipids of the cortical zone with modes of distribution other than those generally seen in hypoplasia of the adrenals. Moreover, it has already been established that corticotropin and cortisone decrease the organism's immunity defenses, facilitate the onset of infections, and render the organism less resistant to them.

- *Complications After Vaccination with BCG. J. F. Droogleever.—p. 2780.
- Ovarian Tumors Producing Virilism. L. Remouchamps and P. F. Ghysbrecht.—p. 2783.

Transmission of Animal Scabies to Man.—According to Stigter scabies may occur in many animals, such as horses, cattle, sheep, monkeys, goats, pigs, dogs, cats and foxes, and these forms of scabies may be transmitted to human subjects. He observed a married couple who complained of itching and in whom skin lesions were discovered at sites typical of infestation with *Sarcoptes scabiei*. Three weeks before, this couple had bought a dog that looked extremely neglected, scratched much, and had bald spots. The veterinary had found *Sarcoptes* mites in the dog, but no mites could be found in the patients. The second instance described also concerned a couple who had taken in a stray cat that had slept in their bed against the shoulder of the man. The skin lesions had begun on this shoulder. Both couples quickly recovered following suitable treatment.

Complications Following Vaccination with BCG.—For some time it was widely assumed that vaccination with BCG involved practically no danger. Follow-up studies on newborn infants given BCG by mouth, however, disclosed a relatively high incidence of complications. The present report reviews investigations carried out on 3,636 adolescents one year after vaccination with BCG. In 0.03% a scar of a perforated suppurative lymphadenitis was observed. Enlargement of the regional lymph nodes caused complaints in 0.8%, and in 6.7% the lymph nodes were enlarged without giving rise to complaints. Conjunctivitis possibly caused by BCG was observed in 0.24%. Erythema nodosum occurred in 0.1%, and 0.4% experienced general malaise of several days duration. However, active pulmonary tuberculosis or tuberculous involvement of the hilar or mediastinal lymph nodes were never observed, and chronic otitis media likewise never occurred as a complication of BCG vaccination.

- *Hemolytic Anemias. K. Aas.—p. 1387.
- Case of Marked Adiposity in Hypothyreosis. O. Ljung.—p. 1396.

Hemolytic Anemia.—Aas concludes that the three main groups of hemolytic anemia—congenital hemolytic anemia, immunological hemolytic anemia, and symptomatic splenogenic anemia—are the most important because of their frequency and because of the therapy available. In congenital hemolytic anemia, treatment consists of splenectomy, which practically always gives excellent clinical results. In the immunohemolytic anemias treatment is primarily concentrated about corticotropin (ACTH) and cortisone. In certain cases, however, splenectomy also will be necessary or desirable to reduce a hemolytic mechanism and to reduce antibody production. Further experiences will probably further clarify lines of guidance for treatment of this group of hemolytic anemias. In the third group, with splenic destruction of the red blood cells, the treatment is splenectomy in suitable cases. It will usually not be possible to cure the basic disease, but a symptomatic improvement of no small value can be attained.

- *New Therapeutic Results of Intra-Arterial Injections of Oxygen in Arteritis of the Lower Limbs. A. Lemaire, J. Loeper and E. Housset.—p. 1439.
- Intracardiac Pressure-Curves in Pericardial Symphysis and Pericarditis. A. Tourniaire, J. Blum, F. Deyrieux and M. Tartufler.—p. 1440.
- Renal Output in Cardiac and Hypertensive Patients. P. Meriel, F. Galinier, R. Sardou and M. Desandre.—p. 1442.

Intra-Arterial Oxygen.—The authors treated 58 patients with arteritis of the legs by means of almost 300 intra-arterial injections of oxygen. There were no mishaps. The simple procedure was carried out with a 50 cc. syringe; the quantity of oxygen injected varied between 50 and 150 cc. Injection was performed only at the level of the single femoral artery with the patient in a horizontal position. In addition to their regular battery of clinical tests and careful interrogation of each patient, the authors used, when necessary, three auxiliary tests enabling them to improve their clinical impression of a given patient. These were measurement of cutaneous temperature and of oxygen in the blood and plethysmography with a photoelectric cell. There were eight failures in this series; seven patients were unimproved, and there was one technical failure because of blood hypercoagulability associated with diabetic arteritis. A definite but transient improvement was observed in 38 patients (some are classified this way because of lack of adequate follow-up, but the average duration of improvement was three to four months). The remaining 12 showed lasting improvement that enabled the patients to lead practically normal lives. The authors find that, in arteritis, the indications for oxygen injection are opposite to those for arterial grafting. While the latter consist mainly of the obliterative forms of the disease, the former include those forms in which the spasmodic element predominates. The existence of dystrophy is not a contraindication to this method that allows of a limitation of scabs and favors scarring.

- *Action of Chlorhydrate of 1-Hydrazinophthalazine on 60 Hypertensives. R. Herbeuval, G. Cuny, R. Guidat and J. Pinck.—p. 1459.
- Malignant Reticulosis of Clinical Type of Periodic Fever. R. Crosnier, A. Darbon, F. Dulac, and others.—p. 1460.
- Action of Chlorpromazine (Largactil) on Tissue Respiration (Oxygen Consumption). L. Peruzzo and R.-B. Forni.—p. 1463.

Action of Chlorhydrate of Hydralazine.—Chlorhydrate of hydralazine (Apresoline) was used in an experimental treatment of 60 hypertensive patients, with the particular purpose of studying its effects on retinal arterial hypertension. The drug was administered orally in four 50 mg. tablets a day for periods of from 25 days to 10 months. On the whole, it was well tolerated. The following results were obtained. Of seven patients with Keith-Wagener stage 1 hypertension, the retinal pressure of one who had arterial and retinal hypertension alone went from 120/60 to 80/20 mm. Hg; of the six with associated peripheral hypertension, five improved and one did not. There were 29 patients with Keith-Wagener stage 2 hypertension; good results were obtained in 22; and 4 had improvement in retinal pressure, 1 in peripheral pressure, and 2 remained unimproved in any way. Patients in stage 3 were divided into those with and those without retinal thrombosis. There were four in the first group, three of whom had improvement in both retinal and peripheral pressure and one of whom had improvement in peripheral pressure only. Of the 17 without thrombosis, there were 15 who had good results and 2 with improvement in peripheral pressure. None of these 57 patients had retinopathy; in the 3 who did, the administration of chlorhydrate of hydralazine must be counted a failure, although faint results on retinal pressure were obtained in 2. The authors feel that, because of its proved beneficial effects on retinal arterial hypertension, on both systolic and diastolic peripheral hypertension, on the subjective manifestations of hypertension, on renal blood flow, and, in some cases, on some cardiovascular signs, chlorhydrate of hydralazine is one of the most valuable drugs known today in essential hypertension and should be given to any hypertensive patient whose renal function is not impaired.

- Effect of Electrocohortin (Compound X) on Water and Electrolytes Excretion Compared with That of Desoxycorticosterone. P. Desaulles, J. Tripod and W. Schuler.—p. 1088.

Cortisone Combined with Phenylbutazone in Polyarthritis.—Combined antirheumatic therapy with cortisone and phenylbutazone (Butazolodin) in three stages was practiced in 20 patients between the ages of 28 and 71 years with primary chronic polyarthritis of two and more years' duration and progression of the disease to stage 3 and 4 according to Steinbrocker's classification (*J. A. M. A.* 140:659 [June 25] 1949). After a preparatory period of two to four weeks during which a first course with phenylbutazone was given parenterally for the relief of acute disturbances, cortisone was instituted for 12 to 20 days with an average total dose of 1,500 mg.; the drug was given in doses of 100 mg. daily for one week, and administration was continued with 75 mg. daily. In a third stage of treatment immediately following that of cortisone therapy, phenylbutazone was given for several months (maximum 11 months); 2.5 to 5 cc. of phenylbutazone was given intramuscularly during the first week and then one ampul every second day or one tablet three to four times daily by mouth. After the second week, the dose was reduced tentatively to one tablet three times daily and finally to one tablet two times daily or one ampul twice a week. The authors strongly caution against simultaneous administration of cortisone and phenylbutazone for prolonged periods that may expose the organism to a phase of deficient production by the adrenal cortex associated with increased susceptibility to infection and toxins that favors the occurrence of toxic allergic side-effects of the pyrazols. Results of the three stage combination treatment with cortisone and phenylbutazone revealed less complaints, subsiding inflammatory manifestations, and definite loosening of joints in all patients during the preparatory period. Further improvement occurred in 17 of the 20 patients during the second, the cortisone stage. At the beginning of the third stage of the treatment, most of the patients first showed certain signs of exacerbation in that the optimum improvement obtained with cortisone could not be maintained; recurrences, however, could be prevented in 55% of the patients and a "marked effect" according to Hench's classification of response was obtained. In 40% of the patients a permanent "moderate effect" was obtained in that the condition of the patients was not entirely satisfactory, but was definitely improved as compared to that before the institution of the treatment. The results were almost exactly identical with those obtained by Ward and associates with cortisone in relatively small doses for prolonged periods (*J. A. M. A.* 152:119 [May 9] 1953). The risk of granulocytopenia requires rigid control of the blood picture. The authors recommend intermittent phenylbutazone administration in that the drug should be discontinued if possible after two to three months and that the entire course of treatment including the initial cortisone administration may be repeated periodically similar to hydrotherapy thus preventing the undesirable side-effects of prolonged cortisone therapy.

Ugeskrift for Laeger, Copenhagen

- *Primary Carcinoma of Fallopian Tube. H. Glastrup.—p. 1497.
- *Cancer of Larynx with Special Regard to Results of Surgical Treatment. J. Falbe-Hansen.—p. 1504.
- Changes in Metabolism Following Operation. H. Faber.—p. 1507.

Primary Carcinoma of Fallopian Tube.—Glastrup traced 20 cases of primary carcinoma of the fallopian tube that occurred in Denmark during the past 10 years. He gives detailed tabulation of 16 of the cases, 11 of which were complicated by other affections. Thirteen patients were between 35 and 60 years of age, and three were between 60 and 71. In spite of the short time of observation, 11 of the 16 are dead, mainly due to cessation of intestinal function or uremia, or have recurrence; of the remaining 5 only 2 have been observed for over five years. Primary carcinoma of the fallopian tube is as insidious as many other forms of cancer and is highly malignant. The symptoms are few and vague. The classic triad of discharge, pain, and bleeding seldom occurs. The objective findings are uncertain, and the disease is often misinterpreted at operation. The characteristic signs at operation are pronounced dilatation of the tube without fissure or rupture and smooth, shiny, and mirror-like serous surface without adhesions or with few adhesions. The tumor spreads along the mucous membrane, without invading the walls, and into the peritoneal cavity or along lymphatic channels. A gynecologic examination in peritoneal disorders is important, even though the symptoms do not directly suggest a genital disorder. Treatment is primarily surgical and consists in removal of uterus, both tubes, both ovaries, and possible lymph nodes. When the carcinoma is established by microscopic examination, it will be evident that the place of excision was infiltrated by the tumor. Reoperation if decided on must be carried out without delay, as the tumor can spread with incredible speed.

Cancer of Larynx with Special Regard to Results of Surgical Treatment.—In 53 cases of cancer of the larynx in 50 men and 3 women, aged from 35 to 85, with diagnosis established by histological examination, Falbe-Hansen performed 5 hemilaryngectomies and 48 total laryngectomies. He emphasizes the importance of general and psychic preoperative treatment. Pulmonary tuberculosis and marked arteriosclerosis are contraindications for operative treatment. Old age is not a contraindication, if the patient is well. Early diagnosis of cancer of the larynx is important both as to life and the functional result of treatment. Small tumors can often be cured by roentgen treatment or removed by hemilaryngectomy. Total laryngectomy and hemilaryngectomy, even when highly developed radiological treatment is available, are indispensable in the treatment of certain forms of cancer of the larynx. Carried out in one session and with prophylactic application of antibiotics, the interventions have a low operative mortality and a good percentage of recoveries. Total laryngectomy is a mutilating but not disabling procedure, as practically all the patients can learn to speak intelligibly with esophagus voice and can get along in widely different occupations. In case of recurrence or rest tumor in patients previously given roentgen treatment that was aimed at minimal harmful effect on the healthy tissue, operation can be done without greater percentage of complications than in patients not given roentgen treatment. In a small country with annually relatively few cases of cancer of the larynx centralization of radiological and surgical treatment is desirable for the best results. Although antibiotic treatment has reduced to a minimum the mortality in operations on the larynx and the operations do not often present difficulties, cases regularly occur in which the operation is especially difficult because of complicating disease or earlier roentgen treatment and in which the results depend to a high degree on the surgeon's experience. The decision of whether a less mutilating operation is justifiable or a larger intervention should be preferred can be made only by an experienced surgeon.

BOOK REVIEWS

The Effects of Noise on Human Behavior. By John F. Corso. WADC Technical Report 5381. Aero Medical Laboratory contract no. AF 33 (616)785, RDO no. 695-61. Paper. Pp. 65, with illustrations. Wright Air Development Center, Air Research and Development Command, United States Air Force, Wright-Patterson Air Force Base, Ohio, 1953.

This report deals with the effects of high intensity noise on human behavior. This is a timely and important topic because of the increasing general concern about noise as an undesirable feature of modern civilization. Extreme claims about "reduction in efficiency" of workers and the production of "nervous breakdowns," etc., by noise are familiar to all. Actual experiments on the effects of noise on human behavior have been few and the results have been quite inconclusive.

The present studies undertook, first, to determine the effects of high intensity noise on human performance as measured by standard mental tests and learning tasks and, second, to investigate certain physiological and psychological characteristics with respect to individual differences in noise susceptibility. The experiments seem technically well controlled and the battery of tests well selected for the purposes as stated. The results are quite clean cut in that they show no marked effect from the noise on short-term mental performance as measured by standard intelligence tests. Small increases in the quantity and decreases in the quality of responses on certain aptitude tests were produced by random bursts of intense noise, but the effects were so small as to be of questionable significance. No effects were demonstrated on tests of learning or recall. There were great individual differences in intellectual performance under the noise, but no personality characteristic was isolated that would predict which persons would show the variations. There was some suggestion of a relation between intellectual performance under noise and certain physiological indicators of activity of the autonomic nervous system, but even here the results cannot be considered definitive.

The noise employed had a fairly flat spectrum of 100 to 3,000 cps and its intensity varied from 100 to 116 db. relative to 0.0002 dyne/cm². This qualifies as a high intensity noise by everyday standards, as it would be quite impossible to communicate by voice in such a noise at 116 db. The noises in question begin to overlap with those industrial noises that seem to cause permanent hearing losses when experienced over years of daily exposure. On the whole the results reported in this summary are negative but they nevertheless have great practical significance.

Community Health Action: A Study of Community Contrast. By Paul A. Miller. With assistance of J. Allan Beegle, et al. Cloth. \$3. Pp. 192, with 10 illustrations. Michigan State College Press, East Lansing, Michigan, 1953.

"Together, the research and this report constitute a detailed review of community action in small American communities. Throughout the study, the accent has been on the community and its resources for citizen-action, rather than on health itself, either environmentally or institutionally. As a comparative study, it threw into relief certain contrasts among the areas studied. Not only were the individual patterns of community action deemed important, but, likewise, the contrasts in patterns."

The authors recognize that community action for the construction and operation of a hospital differs from community action for the development of a local health department or any of several other facilities that it is possible to develop by this means. They also recognize that, regardless of the project, there are certain similarities of pattern in the development of

community organization toward a recognized end and of the "power patterns" in the community that determine the leadership channels for accomplishing the desirable end. After a general discussion of the procedure in this particular research and the general problems associated with "beds, bricks, and people," a careful examination is made of the differences in six regions of the United States. In each instance a hypothetical community, characterizing the communities examined within that region, is described in great detail. The differences in community action and the different organizational patterns typical of the region are described as though they had actually taken place.

This volume should be interesting to all who are concerned with problems of community organization. Since this is specifically concerned with 218 successful community efforts to build hospitals, it will be particularly valuable to those who are beginning to organize their community for a similar activity. Several pages of references, tables containing data of research, and a subject index are included.

The Life and Work of Sigmund Freud. Volume I: The Formative Years and the Great Discoveries, 1856-1900. By Ernest Jones, M.D. Cloth. \$6.75. Pp. 428, with 12 illustrations. Basic Books, Inc., 59 Fourth Avenue, New York 3, 1953.

This biography is to appear in three volumes. Volume 1 deals with Freud's first 44 years of life; it casts light on many obscure theories and dissipates many of the erroneous concepts stated in various other biographies. It is indeed fortunate that Ernest Jones is Freud's biographer. His qualification as such is best gleaned from the following lines in the preface: "The task of compiling a biography of Freud's life is a dauntingly stupendous one. . . . The reasons why I nevertheless yielded to the suggestion that I should undertake it were the considerations pressed on me that I was the only survivor of a small circle of co-workers (the "Committee") in constant intimate contact with Freud, that I had been a close friend for 40 years and also during that period had played a central part in what has been called the "psychoanalytical movement."

The Freud family cooperated with Jones by turning over to him all of the possible information and literary material. This material consisted of about 2,500 letters, including 1,500 written by Freud to his future wife during their four years of engagement, a vast number of miscellaneous letters, official papers, and the published and unpublished letters that Freud wrote to his intimate friend, Wilhelm Fliess. Out of this wealth of material the author has given us an unforgettable portrait of the great psychiatrist. The book should find a wide audience.

Radioactive Isotopes: An Introduction to Their Preparation, Measurement and Use. By W. J. Whitehouse and J. L. Putman. Cloth. \$10. Pp. 424, with 155 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E.C.4, 1953.

Intended primarily for the use of scientific workers, this book offers an introductory summary of the theory of nuclear physics followed by chapters on the production of artificial radioactive isotopes, the various modes of nuclear disintegration, the properties of various ionizing radiations, the modus operandi of cyclotrons and uranium piles, the detection and measurement of radiations, the gross physical effects of radiations, some applications (including uses in archeology) of radioactive isotopes, and the manipulation of radioactive material. Most of the material of interest to physicians is contained in the two last chapters, which include a brief section on recent developments in radiotherapy and an extended, useful discussion of safety problems in radiological laboratories. Written with commendable clarity and authority and provided with good tables, subject index, and author index, the book should be useful to anyone specializing in radiology.

Middle East and Far East. By Allan S. Walker, M.D., Ch.M., F.R.A.C.P. Australia in War of 1939-1945, Series five: Medical. Volume II. Cloth. 35s. Pp. 701, with illustrations. Australian War Memorial, Canberra; obtainable at Anglobooks, 475 Fifth Ave., New York 17, 1953.

This is the second volume in the medical series of the Australian history of World War II. It is, assumedly, a part of the official Australian history of the war, although no direct statement to that effect has been noted either in the book or on the jacket. There is no list of the members of various committees and editorial boards who assisted in this task of writing; however, the editor, Dr. Allen S. Walker, who relinquished his private practice and professional appointments to undertake the editorship, gives credit to a number of officers and others who assisted him. He submitted the chapters to critics fitted by personal experience and knowledge to check the accuracy and fairness of the story. In this laborious task his medical colleagues gave him valuable material and encouragement. Among those to whom he was particularly indebted was Dr. Mervyn Archdall, editor of the *Medical Journal of Australia*. Dr. Walker served with the Australian forces and was also a consulting physician at the Australian medical headquarters and in the field. Here he reviews the sometimes discouraging service in the North African campaign, especially in the retreat from Cyrenaica and at the siege of Tobruk, and in the long period of captivity following the fall of Singapore. The Australian troops bore these hardships with great courage. The editor stresses the purely military activities as a background to the medical activities to a greater extent than is usual in recent medical histories of wars. This fact is more noticeable in the first part of the book, which reviews the service of Australian troops engaged in Africa, Greece, Crete, Syria, and Italy. The last part of the book reviews the period after Japan entered the war, when the Australian forces were diverted toward their homeland and toward Java, Sumatra, and Malaya, a movement which involved the transfer of some 60,000 troops and their equipment. During this transfer, Fifth Column activities were believed to be responsible for the loss of 120 tons of quinine and for the destruction of wheels and headlights on ambulances.

The AIF suffered 2,840 casualties in Java, of whom 751 were killed in action or died while prisoners. It seems strange now to read that, in this phase, quinine was used as a prophylactic against malaria, but the more modern drugs for this purpose were not then available. While the troops were retreating near Rabaul, the day after the troops arrived at Wide Bay, a large party of Japanese soldiers arrived in landing craft and captured over 130 Australians, most of whom they massacred. The victims included most of the field ambulance detachment; despite the brassards on their arms. From Moresby the survivors were taken to the mainland, where it was estimated that out of 252 men, 50 had died of malignant malaria.

During the Japanese attack on Rabaul, a medical captain sick in a hospital chafed at the inadequacy of the plans to evacuate his casualties. He discharged himself from the hospital (in his pajamas), made his way to the fortress, and took charge of the arrangements. Since this captain was not in uniform and wore no brassard, he was taken away as a prisoner to a camp and was never heard of again. He was reported as dead by the Japanese. The editor reviews the campaign in Malaya where the prevention of malaria was given serious consideration. Atabrine was now available as a suppressive drug. In a withdrawal of Australian troops in the Malayan campaign, attempts to rescue the force through a crossroad to Yong Peng failed. Only those of the wounded who could walk made their way back by jungle paths. Trucks containing severely wounded men were fired on by the Japanese. Most of the wounded, the editor says, were massacred by their captors. The final capture of the great British base on Singapore Island is a depressing story. In the final phase of this campaign 500 patients were housed on the lower floors of a 12-story building in which the higher floors were occupied by the headquarters of the Third Indian Corps. The Red Cross flag could not therefore be flown from the building and despite urgent requests from an Australian colonel, the Indian group

refused to move. Consequently the building was shelled and bombed, but the lower floors escaped damage. Protection of medical units by the enemy could usually be expected, but when the Japanese entered the British hospital at Alexandra on Singapore Island, they declared that the area had been used for artillery purposes and they massacred numbers of patients and members of the staff. With the fall of Singapore, about 15,000 Australian troops became prisoners of war, including about 9,000 sick and wounded who were removed to the Shanghai area. The editor's descriptions of the hardships, unsanitary conditions, and inadequate diet, and the heroic efforts to correct them is one of the highlights of this volume, which undoubtedly will be of great interest to Australia and other parts of the British commonwealth. One of the outstanding impressions given is that only younger men, those under 35 years of age, are physically capable of undergoing such hardships as these troops had to endure in the African desert and in the jungles of the Pacific tropical islands.

Antibiotics. By F. A. Robinson, M.Sc. Tech., LL.B., F.R.I.C. Cloth. \$3. Pp. 132. Pitman Publishing Corporation, 2-6 West 45th Street, New York 36; Sir Isaac Pitman & Sons, Ltd., Pitman House, 39-41 Parker Street, Kingsway, London, WC2; 381-383 Church Street, Toronto, 1953.

This British publication is a new monograph dealing with all the antibiotics in common use. It is divided into chapters according to individual or closely related antibiotics, or according to their derivation from molds or bacteria. Each chapter deals with such aspects as methods of production, assay, antimicrobial spectrum, pharmacology, absorption and excretion, clinical use, preparations, chemical structure, and synthesis. The space devoted to manufacturing procedures, chemistry, and bacteriology greatly exceeds the space given to pharmacological and clinical information. Because of the rapidly changing developments in the antibiotic field, the book is out-of-date from the standpoint of current therapeutic knowledge in the United States. Historically, much of the basic information will be of interest to workers in the antibiotic field. Its appeal to American readers will be diminished by the use of British terminology, especially in the nomenclature for micro-organisms. An index is provided. The printing is clear; the binding is only fair. This book cannot be recommended for practicing physicians but will be useful to students as a reference.

Symptoms of Visceral Disease: A Study of the Vegetative Nervous System in Its Relationship to Clinical Medicine. By Francis Marion Pottenger, A.M., M.D., LL.D., Medical Director, Pottenger Sanatorium and Clinic for Diseases of Chest, Monrovia, California. Seventh edition. Cloth. \$7.50. Pp. 446, with 97 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

This book was first published in 1919, and the sixth edition was published in 1944. The author has been a student of medicine and a careful observer of the symptoms and signs presented by his patients for over 50 years. He hopes that this new edition "will continue to be helpful to those who are especially interested in the visceral reactions of man to stimuli, no matter from what source they come." In dedicating this book he states, "There is a patient who has the disease, as well as the disease which has the patient." Part 1 takes up the vegetative nervous system, and it is first considered embryologically and anatomically and then discussed from the physiological and the pharmacological viewpoint. This is done in a manner that should be interesting and helpful to a clinician. Part 2 discusses the relationship between the vegetative nervous system and the symptoms of visceral disease. Symptoms due to toxemia, reflex causes, and the disease process per se are separated. Part 3 considers the innervations of important viscera with a clinical study of the more important viscerogenic reflexes. This portion of the book focuses the vast amount of information discussed in earlier chapters on the specific part of the body under consideration. The heart, stomach, pancreas, eyes, larynx, and other organs are taken up in separate chapters. These should be valuable to anyone trying to understand the symptoms and signs of disease. The book is written interestingly and is well illustrated. There are references after each chapter, but few of these are recent.

BOOK REVIEWS

The Effects of Noise on Human Behavior. By John F. Corso. WADC technical report 53-81. Aero Medical Laboratory contract no. AF 33 (038)-786, RDO no. 695-63. Paper. Pp. 65, with illustrations. Wright Air Development Center, Air Research and Development Command, United States Air Force, Wright-Patterson Air Force Base, Ohio, 1953.

This report deals with the effects of high intensity noise on human behavior. This is a timely and important topic because of the increasing general concern about noise as an undesirable feature of modern civilization. Extreme claims about "reduction in efficiency" of workers and the production of "nervous breakdowns," etc., by noise are familiar to all. Actual experiments on the effects of noise on human behavior have been few and the results have been quite inconclusive.

The present studies undertook, first, to determine the effects of high intensity noise on human performance as measured by standard mental tests and learning tasks and, second, to investigate certain physiological and psychological characteristics with respect to individual differences in noise susceptibility. The experiments seem technically well controlled and the battery of tests well selected for the purposes as stated. The results are quite clean cut in that they show no marked effect from the noise on short-term mental performance as measured by standard intelligence tests. Small increases in the quantity and decreases in the quality of responses on certain aptitude tests were produced by random bursts of intense noise, but the effects were so small as to be of questionable significance. No effects were demonstrated on tests of learning or recall. There were great individual differences in intellectual performance under the noise, but no personality characteristic was isolated that would predict which persons would show the variations. There was some suggestion of a relation between intellectual performance under noise and certain physiological indicators of activity of the autonomic nervous system, but even here the results cannot be considered definitive.

The noise employed had a fairly flat spectrum of 100 to 3,000 cps and its intensity varied from 100 to 116 db. relative to 0.0002 dyne/cm². This qualifies as a high intensity noise by everyday standards, as it would be quite impossible to communicate by voice in such a noise at 116 db. The noises in question begin to overlap with those industrial noises that seem to cause permanent hearing losses when experienced over years of daily exposure. On the whole the results reported in this summary are negative but they nevertheless have great practical significance.

Community Health Action: A Study of Community Contrast. By Paul A. Miller. With assistance of J. Allan Beegle, et al. Cloth. \$3. Pp. 192, with 10 illustrations. Michigan State College Press, East Lansing, Michigan, 1953.

"Together, the research and this report constitute a detailed review of community action in small American communities. Throughout the study, the accent has been on the community and its resources for citizen-action, rather than on health itself, either environmentally or institutionally. As a comparative study, it threw into relief certain contrasts among the areas studied. Not only were the individual patterns of community action deemed important, but, likewise, the contrasts in patterns."

The authors recognize that community action for the construction and operation of a hospital differs from community action for the development of a local health department or any of several other facilities that it is possible to develop by this means. They also recognize that, regardless of the project, there are certain similarities of pattern in the development of

community organization toward a recognized end and of the "power patterns" in the community that determine the leadership channels for accomplishing the desirable end. After a general discussion of the procedure in this particular research and the general problems associated with "beds, bricks, and people," a careful examination is made of the differences in six regions of the United States. In each instance a hypothetical community, characterizing the communities examined within that region, is described in great detail. The differences in community action and the different organizational patterns typical of the region are described as though they had actually taken place.

This volume should be interesting to all who are concerned with problems of community organization. Since this is specifically concerned with 218 successful community efforts to build hospitals, it will be particularly valuable to those who are beginning to organize their community for a similar activity. Several pages of references, tables containing data of research, and a subject index are included.

The Life and Work of Sigmund Freud. Volume I: The Formative Years and the Great Discoveries, 1856-1900. By Ernest Jones, M.D. Cloth. \$6.75. Pp. 428, with 12 illustrations. Basic Books, Inc., 59 Fourth Avenue, New York 3, 1953.

This biography is to appear in three volumes. Volume 1 deals with Freud's first 44 years of life; it casts light on many obscure theories and dissipates many of the erroneous concepts stated in various other biographies. It is indeed fortunate that Ernest Jones is Freud's biographer. His qualification as such is best gleaned from the following lines in the preface: "The task of compiling a biography of Freud's life is a dauntingly stupendous one. . . . The reasons why I nevertheless yielded to the suggestion that I should undertake it were the considerations pressed on me that I was the only survivor of a small circle of co-workers (the "Committee") in constant intimate contact with Freud, that I had been a close friend for 40 years and also during that period had played a central part in what has been called the "psychoanalytical movement."

The Freud family cooperated with Jones by turning over to him all of the possible information and literary material. This material consisted of about 2,500 letters, including 1,500 written by Freud to his future wife during their four years of engagement, a vast number of miscellaneous letters, official papers, and the published and unpublished letters that Freud wrote to his intimate friend, Wilhelm Fliess. Out of this wealth of material the author has given us an unforgettable portrait of the great psychiatrist. The book should find a wide audience.

Radioactive Isotopes: An Introduction to Their Preparation, Measurement and Use. By W. J. Whitehouse and J. L. Putman. Cloth. \$10. Pp. 424, with 155 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E.C.4, 1953.

Intended primarily for the use of scientific workers, this book offers an introductory summary of the theory of nuclear physics followed by chapters on the production of artificial radioactive isotopes, the various modes of nuclear disintegration, the properties of various ionizing radiations, the modus operandi of cyclotrons and uranium piles, the detection and measurement of radiations, the gross physical effects of radiations, some applications (including uses in archeology) of radioactive isotopes, and the manipulation of radioactive material. Most of the material of interest to physicians is contained in the two last chapters, which include a brief section on recent developments in radiotherapy and an extended, useful discussion of safety problems in radiological laboratories. Written with commendable clarity and authority and provided with good tables, subject index, and author index, the book should be useful to anyone specializing in radiology.

Middle East and Far East. By Allan S. Walker, M.D., Ch.M., F.R.A.C.P. *Australia in War of 1939-1945, Series five: Medical.* Volume II. Cloth. 35s. Pp. 701, with illustrations. Australian War Memorial, Canberra; obtainable at Anglobooks, 475 Fifth Ave., New York 17, 1953.

This is the second volume in the medical series of the Australian history of World War II. It is, assumedly, a part of the official Australian history of the war, although no direct statement to that effect has been noted either in the book or on the jacket. There is no list of the members of various committees and editorial boards who assisted in this task of writing; however, the editor, Dr. Allen S. Walker, who relinquished his private practice and professional appointments to undertake the editorship, gives credit to a number of officers and others who assisted him. He submitted the chapters to critics fitted by personal experience and knowledge to check the accuracy and fairness of the story. In this laborious task his medical colleagues gave him valuable material and encouragement. Among those to whom he was particularly indebted was Dr. Mervyn Archdall, editor of the *Medical Journal of Australia*. Dr. Walker served with the Australian forces and was also a consulting physician at the Australian medical headquarters and in the field. Here he reviews the sometimes discouraging service in the North African campaign, especially in the retreat from Cyrenaica and at the siege of Tobruk, and in the long period of captivity following the fall of Singapore. The Australian troops bore these hardships with great courage. The editor stresses the purely military activities as a background to the medical activities to a greater extent than is usual in recent medical histories of wars. This fact is more noticeable in the first part of the book, which reviews the service of Australian troops engaged in Africa, Greece, Crete, Syria, and Italy. The last part of the book reviews the period after Japan entered the war, when the Australian forces were diverted toward their homeland and toward Java, Sumatra, and Malaya, a movement which involved the transfer of some 60,000 troops and their equipment. During this transfer, Fifth Column activities were believed to be responsible for the loss of 120 tons of quinine and for the destruction of wheels and headlights on ambulances.

The AIF suffered 2,840 casualties in Java, of whom 751 were killed in action or died while prisoners. It seems strange now to read that, in this phase, quinine was used as a prophylactic against malaria, but the more modern drugs for this purpose were not then available. While the troops were retreating near Rabaul, the day after the troops arrived at Wide Bay, a large party of Japanese soldiers arrived in landing craft and captured over 130 Australians, most of whom they massacred. The victims included most of the field ambulance detachment, despite the brassards on their arms. From Moresby the survivors were taken to the mainland, where it was estimated that out of 252 men, 50 had died of malignant malaria.

During the Japanese attack on Rabaul, a medical captain sick in a hospital chafed at the inadequacy of the plans to evacuate his casualties. He discharged himself from the hospital (in his pajamas), made his way to the fortress, and took charge of the arrangements. Since this captain was not in uniform and wore no brassard, he was taken away as a prisoner to a camp and was never heard of again. He was reported as dead by the Japanese. The editor reviews the campaign in Malaya where the prevention of malaria was given serious consideration. Atabrine was now available as a suppressive drug. In a withdrawal of Australian troops in the Malayan campaign, attempts to rescue the force through a crossroad to Yong Peng failed. Only those of the wounded who could walk made their way back by jungle paths. Trucks containing severely wounded men were fired on by the Japanese. Most of the wounded, the editor says, were massacred by their captors. The final capture of the great British base on Singapore Island is a depressing story. In the final phase of this campaign 500 patients were housed on the lower floors of a 12-story building in which the higher floors were occupied by the headquarters of the Third Indian Corps. The Red Cross flag could not therefore be flown from the building and despite urgent requests from an Australian colonel, the Indian group

refused to move. Consequently the building was shelled and bombed, but the lower floors escaped damage. Protection of medical units by the enemy could usually be expected, but when the Japanese entered the British hospital at Alexandra on Singapore Island, they declared that the area had been used for artillery purposes and they massacred numbers of patients and members of the staff. With the fall of Singapore, about 15,000 Australian troops became prisoners of war, including about 9,000 sick and wounded who were removed to the Shanghai area. The editor's descriptions of the hardships, unsanitary conditions, and inadequate diet, and the heroic efforts to correct them is one of the highlights of this volume, which undoubtedly will be of great interest to Australia and other parts of the British commonwealth. One of the outstanding impressions given is that only younger men, those under 35 years of age, are physically capable of undergoing such hardships as these troops had to endure in the African desert and in the jungles of the Pacific tropical islands.

Antibiotics. By F. A. Robinson, M.Sc. Tech., LL.B., F.R.I.C. Cloth. \$3. Pp. 132. Pitman Publishing Corporation, 2-6 West 45th Street, New York 36; Sir Isaac Pitman & Sons, Ltd., Pitman House, 39-41 Parker Street, Kingsway, London, WC2; 381-383 Church Street, Toronto, 1953.

This British publication is a new monograph dealing with all the antibiotics in common use. It is divided into chapters according to individual or closely related antibiotics, or according to their derivation from molds or bacteria. Each chapter deals with such aspects as methods of production, assay, antimicrobial spectrum, pharmacology, absorption and excretion, clinical use, preparations, chemical structure, and synthesis. The space devoted to manufacturing procedures, chemistry, and bacteriology greatly exceeds the space given to pharmacological and clinical information. Because of the rapidly changing developments in the antibiotic field, the book is out-of-date from the standpoint of current therapeutic knowledge in the United States. Historically, much of the basic information will be of interest to workers in the antibiotic field. Its appeal to American readers will be diminished by the use of British terminology, especially in the nomenclature for micro-organisms. An index is provided. The printing is clear; the binding is only fair. This book cannot be recommended for practicing physicians but will be useful to students as a reference.

Symptoms of Visceral Disease: A Study of the Vegetative Nervous System in Its Relationship to Clinical Medicine. By Francis Marion Pottenger, A.M., M.D., LL.D., Medical Director, Pottenger Sanatorium and Clinic for Diseases of Chest, Monrovia, California. Seventh edition. Cloth. \$7.50. Pp. 446, with 97 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

This book was first published in 1919, and the sixth edition was published in 1944. The author has been a student of medicine and a careful observer of the symptoms and signs presented by his patients for over 50 years. He hopes that this new edition "will continue to be helpful to those who are especially interested in the visceral reactions of man to stimuli, no matter from what source they come." In dedicating this book he states, "There is a patient who has the disease, as well as the disease which has the patient." Part 1 takes up the vegetative nervous system, and it is first considered embryologically and anatomically and then discussed from the physiological and the pharmacological viewpoint. This is done in a manner that should be interesting and helpful to a clinician. Part 2 discusses the relationship between the vegetative nervous system and the symptoms of visceral disease. Symptoms due to toxemia, reflex causes, and the disease process per se are separated. Part 3 considers the innervations of important viscera with a clinical study of the more important viscerogenic reflexes. This portion of the book focuses the vast amount of information discussed in earlier chapters on the specific part of the body under consideration. The heart, stomach, pancreas, eyes, larynx, and other organs are taken up in separate chapters. These should be valuable to anyone trying to understand the symptoms and signs of disease. The book is written interestingly and is well illustrated. There are references after each chapter, but few of these are recent.

Human Embryology. By Bradley M. Patten, Professor of Anatomy in University of Michigan Medical School, Ann Arbor. Second edition. Cloth. \$12. Pp. 798, with 455 illustrations. Blakiston Company (division of Doubleday & Company, Inc.), 575 Madison Ave., New York 22, 1953.

The aim of this book was to develop those aspects of embryology that form an important background for the other medical sciences, especially obstetrics and gynecology. In this edition the author rewrote the chapter on cleavage, germ layers, and establishment of the embryonic body, basing his new data on the early human embryos described by Hertig and Rock, rather than on inference from conditions in other mammals. Likewise, the data about the early stages of human implantation presented by the same investigators led to extensive changes in the chapter on the fetal membranes and the placenta. Because of the progress in the surgical treatment of congenital cardiovascular defects, a number of additional illustrations of congenital defects was added. This book contains practically all the useful knowledge we possess about human embryology. The material is presented in an interesting, easily readable style. The illustrations are numerous, clear, and highly instructive. Many were taken from other sources but are valuable additions. At the end of the book is an extensive bibliography. This book will long remain a classic in its field.

Eden & Holland's Manual of Obstetrics. By Alan Brews, M.D., M.S., M.R.C.P., Obstetric and Gynecological Surgeon, London Hospital, London. Tenth edition. Cloth. 52s. 6d. Pp. 812, with 435 illustrations. J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W.1, 1953.

This standard British text is highly recommended. It is a manual rather than a compendium of knowledge. Although it is impossible to cover all of the rapidly accumulating literature, Brews has made his selections admirably. At first glance, the text seems superficial on many topics, but more careful analyses will not sustain that idea. The guide to further reading at the end of each chapter captures one's attention and accomplishes its purpose far better than a stereotyped list of references. The guide lists British references predominantly. The author frequently comments on the high quality of pertinent references, further stimulating the student's interest in source reading. The undergraduate needs no other text to qualify for examinations, and the practitioner and specialist will find a well-selected bibliography readily at hand.

Courage Is the Key. Edited by Alexander Klein. Cloth. \$3.75. Pp. 287. Twayne Publishers, 34 East 23rd Street, New York 10, 1953.

Not long ago, while browsing through the essays of William James, the philosopher, the editor of this anthology was moved to action by the statement, "We draw new life from the heroic example." This sentence inspired him to seek out representative heroic examples—accounts of the physical and spiritual adventures of both famous and little-known men and women who exemplified the undefeated, triumphant human spirit in the face of severe physical, psychological, economic, and social blows. These persons, subjected to extraordinary trials and suffering, not only overcame the handicaps imposed on them but in the process became far better human beings than they had been before catastrophe struck. The stories, written in fast-paced journalistic tempo, deal with such handicaps as arthritis, heart disease, poliomyelitis, cerebral palsy, blindness, deafness, epilepsy, amputation, and paralysis. The reader will find this book a testament to the undefeated human spirit.

Essentials of Abnormal Child Psychology: A Survey Representing Twenty-Five Years' Work in the Field of Child Psychology. By Dr. Ernest Harms. Cloth. \$5. Pp. 265. Julian Press, Inc., 8 W. 40th St., New York 18, 1953.

The author of this survey of the nature and origins of mental abnormalities has had long training and experience both here and abroad and has worked with Freud, Kraepelin, Jung, and Adler. He interprets the diverse opinions concerning the cause of behavioral abnormalities in children. The book is strong in its careful consideration of the many psychoanalytic writers in the field; its major weakness lies in the author's inevitable acceptance of the analytic interpretation over any other. It calls attention to many areas not widely discussed in the litera-

ture, such as the use of child art in diagnosis and the use of "autogenic therapy" in treating children's problems. Although not complete in its coverage of the behavior disorders in childhood schizophrenia and childhood hysteria, depressive and manic disease in childhood, and the abnormal and normal child, infrequently discussed subjects such as ego inflation and ego deflation in childhood and the Mignon neurosis are dealt with adequately. One or two rather naïve statements concerning the phonetic analysis of the patient's speech suggest that the author is more at home with analytical discussion than with the analysis of language. The book contains highly technical psychiatric phraseology, but it will interest all physicians and psychologists working with the psychological problems of children.

Health Yearbook 1953. Compiled by Oliver E. Byrd, Ed.D., M.D., F.A.P.H.A., Professor of Health Education, and Director, Department of Hygiene, School of Education, Stanford University, Stanford, California. Foreword by David K. Brace, Chairman of Department of Physical and Health Education, University of Texas, Austin. Cloth. \$3.50. Pp. 280. Stanford University Press, Stanford, California; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, 1953.

Despite a slight change in title, this yearbook follows the pattern of former volumes in presenting abstracts of articles relating to medicine and health education. Most of the material abstracted appeared between July 1, 1952, and June 30, 1953. A total of 101 professional publications provided the source material. The book contains an extensive bibliography, a list of the sources, an author index, and a subject index. Although there is no pretense of complete coverage of the field, a wide range of topics that are of general interest is provided. Each chapter begins with a general summary of the current status of the topic, in which the editor avoids any attempt at interpretation. This volume should be helpful to a wide variety of health education workers. On the jacket is a short quiz patterned after a procedure introduced by the publishers about 10 years ago.

The Autonomic Nervous System. By Albert Kuntz, Ph.D., M.D., Professor of Anatomy in St. Louis University School of Medicine, St. Louis. Fourth edition. Cloth. \$10. Pp. 605, with 94 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

This book has long served as the standard reference text on the autonomic nervous system. It covers in great detail the autonomic innervation of the viscera and the functional effects of stimulation or depression of the sympathetic and parasympathetic components. The microscopic anatomy of normal and pathological autonomic ganglion cells is considered in detail. Autonomic centers in the central nervous system are adequately discussed and the concept of chemical mediation of autonomic nerve impulses is touched on briefly. The concluding 100 pages of the book are devoted to a consideration of the role of the autonomic nervous system in various diseases and to surgical procedures involving the autonomic nervous system. An extensive bibliography is included.

Physical Medicine and Rehabilitation. Edited by Basil Kiernander, M.B., B.S., M.R.C.P., Director, Physical Medicine Department, Hospital for Sick Children, Great Ormond Street, London. With introduction by Rt. Hon. Lord Horder, G.C.V.O., M.D., F.R.C.P., President, British Association of Physical Medicine. Cloth. \$12.75. Pp. 610, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

The work of 26 contributors from Great Britain, Canada, and the United States has been combined in this book. Chapters are devoted to a review of the fundamental anatomy and physiology most pertinent to physical medicine and rehabilitation and to psychiatric aspects, care of the injured, geriatrics, rheumatology, neurology, pediatrics, dermatology, pulmonary disease, heart disease, and orthopedic surgery as they apply to this field. There is also a chapter on vocational rehabilitation. Since the book includes viewpoints from three countries it does not present a unanimity of opinion and there is some repetition. This enhances rather than detracts from the value of the book. Every physician, regardless of whether he limits his practice, will find this volume a particularly valuable reference source.

QUERIES AND MINOR NOTES

THE GLYCERIN SUPPOSITORY HABIT

TO THE EDITOR:—*A healthy man of 38 is habituated to the use of plain glycerin suppositories to induce bowel movements. He began three years ago when he had to leave his home at irregular, sometimes very early hours. Now he will not, or cannot, move his bowels without the suppository. The anus is normal, and there is good sphincter contractility. The feces are normally formed. Can the use of these suppositories lead to ill-effects?* M.D., New York.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

ANSWER.—This consultant has never seen any chronic local irritation other than an occasional mild erythema of the anoderm as a result of the habitual use of glycerin suppositories. True, glycerin may be considered as an irritant, but its contact with the anal canal is so transitory in this instance that this man probably should not be concerned.

ANSWER.—The continued use of glycerin suppositories is inadvisable. It is irritating and perpetuates a practice of initiating bowel movements that can be done better by more acceptable methods. The physician should first attempt to eliminate any underlying causes such as emotional tension, unsuitable diets, and organic disease.

The establishment of orderly bowel habits even at the expense of a little extra time in the morning is perhaps one of the most important factors in the average case encountered in general practice. Generally, a leisurely breakfast in a relaxing environment is followed by a desire to defecate. In some normal persons this may occur as often as once after each meal, owing to the gastrocolic reflex. Dietary aids include at least 2 qt. (2,000 cc.) of fluid daily for the adult, fruits or fruit juices (e. g., prune, apple, banana) at every meal, two green vegetables twice daily, and whole wheat bread or cereals. These may be supplemented by the B complex vitamins.

For temporary or occasional use, the hydrophilic colloids, mineral oil, or the magnesium salts are helpful but should never replace psychological and dietary considerations. In some patients there is a tendency for inspissated fecal material to accumulate in the ampulla in a manner amounting almost to an impaction. Then the use of olive oil is advisable in amounts of 1 to 4 oz. (30 to 120 cc.) instilled into the rectum before retiring and left in place overnight. If ineffective, it is supplemented by two tablespoonfuls (30 cc.) of mineral oil by mouth.

Exercise is important, particularly in patients with sedentary occupations. The diaphragm and abdominal muscles are the principal extra-enteric factors in the physiological mechanism of defecation. Bending, breathing exercises, and walking are recommended.

COFFEE WITH OR WITHOUT CREAM

TO THE EDITOR:—*Does black coffee have any more stimulating effect on the nervous system than coffee with cream?*

M.D., Michigan.

ANSWER.—No. Black coffee may be a little more concentrated but the addition of cream does not alter its chemical composition. Any differences noted are due to concentration and speed of absorption, not to any qualitative differences between the two samples of coffee.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

CARDIAC PATIENTS AT HIGH ALTITUDES

TO THE EDITOR:—*What is the effect of altitude on a cardiac patient who is kept well compensated on digitoxin? I have a patient who has spent his whole life in Arkansas at near sea level who wishes to vacation in Colorado at an altitude of 5,000 to 10,000 ft. for a week or two. He weighs 240 lb. at a height of 5 ft. 5 in. He has a moderate degree of pulmonary fibrosis, occasional runs of extrasystoles, and a mean blood pressure of 140/86 mm. Hg. Would such an excursion be harmful?*

Edward J. Novak, M.D., Tuckerman, Ark.

ANSWER.—The vast majority of cardiac patients can visit Colorado cities at an altitude of under 6,500 ft. with no difficulties. Many from the beginning, and most after a week or two, notice no special difference. An occasional patient feels that he is definitely shorter of breath on very mild exertion. On the other hand, many believe they feel better—possibly because of other climatic factors or just because they are on vacation. It is probably unwise for cardiac patients to come from sea level directly to altitudes over 7,000 ft., although many do and feel very well and have no difficulties. In any case, and especially in going to altitudes over 7,000 ft., physical activity should be limited the first couple of weeks. Trips in an auto over passes 10,000 ft. high do not seem to be any problem, but staying overnight at high altitudes should be avoided until there has been some acclimatization.

DIVERTICULUM IN AN INFANT

TO THE EDITOR:—*I saw an autopsy the other day on a baby about 1 year old. It had a diverticulum, and the tip was adhered to the mesentery and quite inflamed with several nodes. The bowel was tucked through the loop several times but circulation was good. The abdomen was not distended. The baby died suddenly. There was no fluid in the peritoneal cavity. Would there be enough toxicity even if the bowel was not strangulated to be fatal?*

H. D. Thomas, M.D., Belleville, Kan.

ANSWER.—It is assumed that the question is regarding Meckel's diverticulum. Such a diverticulum may originate in any segment of the intestine. It is assumed also that in this case the diverticulum originated in the ileum. It is not unusual to find the tip of such a diverticulum fixed or adherent to the mesentery of another segment of the intestine, thus forming a loop. Through such a loop, many segments of intestine or bowel may become fixed. The inquirer emphasized three postmortem findings: 1. The diverticulum did form such a loop into which segments of bowel were found. 2. Circulation to the intestine was apparently good, since there was no distention of the abdomen. 3. There were enlarged nodes in the mesentery. Assuming that there was some heterotopic gastric mucosa in the diverticulum that caused a small ulceration not unlike a gastric ulcer, there would be considerable inflammatory reaction around the diverticulum and also enlarged nodes in the mesentery. Since a large percentage of children, even though apparently quite normal, have marked enlargement of the mesenteric nodes, nodal enlargement may or may not have resulted from the presence of a Meckel's diverticulum. The fact that the abdomen was not distended and there was no evidence of intestinal obstruction would lead one to believe from a clinical standpoint death was not due to intestinal obstruction. Therefore, since no strangulation was present, it seems doubtful that one could say that a toxic condition (which in this case should be imbalance in blood chemistry) was present. In other words, it is not possible to state the cause of death in this case.

ENCEPHALITIS COMPLICATING MEASLES

TO THE EDITOR:—Some time ago a patient came in with a child who had encephalitis following measles, and they brought along an article from Better Homes and Gardens concerning this condition. I was unable to give them any information concerning treatment, and they were very upset. The child had measles at the age of 17 months, and he has never developed mentally. I might mention that there are some mentally deranged persons in the families of both the parents. I will appreciate an opinion on this case.

M.D., South Carolina.

ANSWER.—Encephalitis as a complication of measles has been variously estimated to occur in from 1 in 1,000 reported cases of measles to as high as 1 in 428 reported cases (Hoyne, A. L., and Slotkowski, E. L.: *Am. J. Dis. Child.* 73:554 [May] 1947). When measles encephalitis develops it is nearly always during the period of the eruption and only rarely before the rash is present or after it has disappeared. In some of the series reported, the fatality rate has been as high as 33⅓% and an additional one-third had permanent mental defects. The article mentioned by the parents of the child probably referred to Knouf and Bower's report presented at the last American Medical Association Annual Meeting in New York. It was stated that remarkable recoveries were brought about, even in cases of long-standing, by means of typhoid vaccine injections. This form of shock treatment was at one time used quite extensively in mental institutions. On the basis of your patient's family history, one might wonder whether the child was normal mentally prior to having measles. Sometimes parents of mentally defective children who were abnormal at birth gain a certain degree of satisfaction by attributing deficiencies to an acute infectious disease that was acquired in infancy or early childhood.

COOLEY'S ANEMIA

TO THE EDITOR:—A girl, 12 years of age, has been suffering from Cooley's erythroblastic anemia, and has been under treatment by several physicians since infancy. She has received frequent transfusions of whole blood. Recently she has been receiving 200 mg. of cortisone orally daily. Has any new therapy for this condition been developed?

Albert I. Clark, M.D., Shreveport, La.

ANSWER.—Unfortunately there is no new treatment for Cooley's anemia. Cortisone and corticotropin have not been proved to be of value. Splenectomy is usually not helpful because the defect or abnormality is in the red blood cell itself. However, there are some instances in which secondary "hypersplenism" seems to have developed and to have accelerated the rate of red cell destruction even more (*J. Clin. Invest.* 32:1236 [Dec.] 1953.) Under these circumstances, transfusion requirements would become greater and splenectomy should prove beneficial. Detailed hematological studies; however, including measurement of the survival of normal cells transfused into the patients with Cooley's anemia, would be required in order to identify the secondary "hypersplenism." There is as yet no simpler way to arrive at the diagnosis under these circumstances.

MULTIPLE LIPOMAS

TO THE EDITOR:—What is the latest treatment for multiple subcutaneous lipomas? My patient is a 37-year-old man. Would an injection of hyaluronidase (Alidase) help? His tumors at times become painful, and they are excised.

A. B. Vlahakos, M.D., Pasadena, Texas.

ANSWER.—Subcutaneous lipomas that grow rapidly or become tender or painful should be excised, but otherwise they should only be observed. A differential diagnosis should be established to exclude nonsuppurative relapsing panniculitis, which is sometimes helped by antibiotics. Because of the relatively low vascularity, injection seems contraindicated as it is likely to result in fat necrosis and not to help the major problem.

NPH INSULIN

TO THE EDITOR:—What is meant by the term NPH insulin; also what is the accepted minimum, moderate, moderately large and large doses, in units of insulin, taken daily, in either one injection or multiple injections?

George J. Korby, M.D., Detroit.

ANSWER.—The alphabetical designation "NPH" in the name NPH insulin is derived from the initial letters of the term "neutral protamine Hagedorn." The last word in this group is the name of the Danish investigator in whose laboratory the product was first developed. In accordance with previous action taken by the U.S.P. Insulin Advisory Board, this form of insulin has been designated isophane insulin and the term NPH insulin was retained as a synonym. It is understood that this terminology may be reconsidered by the U.S.P. board. New and Nonofficial Remedies, 1953, describes the actions and uses of the preparation under the present terminology as follows:

"Essentially, isophane insulin is a modification of protamine zinc insulin, but it differs in containing less protamine, more zinc and in being crystalline rather than amorphous in character. The pharmacologic action of isophane insulin is similar to that of the other insulins. Its blood sugar lowering action places it in an intermediate position between globin insulin and protamine zinc insulin. The onset of action for isophane insulin begins usually 2 hours after subcutaneous injection, whereas 6 to 8 hours are required for protamine zinc insulin. Its peak effect occurs 10 to 20 hours after administration, and its duration of action is 28 to 30 hours.

"Isophane insulin may be mixed with regular insulin. Loss of quick action of regular insulin is less with isophane insulin than with similar mixtures of protamine zinc insulin, because isophane insulin contains less available protamine. Used in conjunction with regulation of diet and exercise, this form of insulin is of value in control of severe and labile diabetes. It is not recommended for children below 5 years of age or for patients who require quick-acting insulin."

Since the time of administration, number of doses, and amount of solution must be determined by the needs of the individual patient, in accordance with accurate dietary regulation and clinical study, it is not feasible to state precisely the "accepted minimum, moderate, moderately large and large" daily dose in terms of units of insulin. The report of Henry T. Ricketts (*J. A. M. A.* 150:959 [Nov. 8] 1952) suggests it is best to begin with not more than 10 to 20 units of isophane insulin daily, given one-half hour before breakfast; the dose is then raised 3 to 5 units every three to five days until the urine specimen on rising or the afternoon specimen is sugar-free or nearly so. He also states, "If glycosuria persists after breakfast, 5 to 10 units of crystalline insulin is mixed with the NPH insulin taken before breakfast. If glycosuria persists after supper, a small dose of crystalline insulin may be necessary before that meal. A short-acting insulin should never be given at bedtime when a long-acting preparation is being used."

MAN'S NONFERTILE PERIODS

TO THE EDITOR:—Is there any age at which the human male is considered to be incapable of reproduction?

Jan W. Crow, M.D., San Diego, Calif.

ANSWER.—The time of nonfertility in men varies with racial groups and the individual. Obviously, the nonfertile period starts with birth and continues until the age when fertile sperm are manufactured by the body and the body is capable of emitting them. In this country the average age when this occurs is about 14 or 15 years. This is, of course, followed by a period of potential fertility that ends at the time the body ceases to manufacture fertile sperm and loses its ability to emit them. This generally varies greatly. If one had to assign an age to it, 65 would probably be near the average time when that occurs. There are exceptions, as in an authenticated case recorded, in which fertility remained until the age of 94.

BLOOD CELL COUNTS

TO THE EDITOR:—In a blood cell count done as part of a complete routine periodic health examination, what should be the dividing line below which or above which a recommendation should be made for further evaluation and treatment?

M.D., Pennsylvania.

ANSWER.—The moderately wide range in values for the cellular elements of blood in apparently normal, healthy persons makes a precise answer to this question difficult. The following figures given by Wintrobe are fairly representative of the values reported by various authors for adult human subjects:

	Men	Women
Red blood cell count (millions/cu. mm.)....	5.4 ± 0.8	4.8 ± 0.6
Hemoglobin (gm./100 cc.).....	16 ± 2	14 ± 2
Total leukocytes (per cu. mm.).....	5,000 to 10,000	
Segmented neutrophils	54 to 62%	
Lymphocytes	25 to 33%	
Monocytes	3 to 7%	
Eosinophils	1 to 3%	

Even these ranges include only about 95% of the results on normal subjects. Furthermore, other factors must be taken into consideration. Persons who live at altitudes of 5,000 ft. or more have higher red blood cell and hemoglobin levels. The excitement of a health examination, any emotional disturbance, or physical activity immediately preceding the study may elevate the leukocyte count above 10,000. Technical error is greater than most physicians realize. An increase in the number of reported lymphocytes is more commonly caused by the fact that some technicians examine only the center of blood films than by any other factor.

If all these facts are taken into consideration, then the following rough generalizations can be made. In women, red blood cell counts below 4 and above 6 million per cubic millimeter and hemoglobin levels below 11 or above 17 gm. per 100 cc. require further evaluation. Similar values for young adult men would be below 4.2 or above 6.5 million for red cells, and below 12 or above 18 gm. for hemoglobin. In men above the age of 40, erythrocyte counts above 6 million should probably be regarded with suspicion. Leukocyte levels below 4,000 or above 12,000 per cubic millimeter should lead to further study. The same may be said for percentages of lymphocytes greater than 50, of monocytes greater than 15, of basophils above 5, and of eosinophils above 10. For values between these figures and those given in tabular form above, the presence or absence of other manifestations and clinical judgment must guide the examiner.

USE OF VITAMIN D IN RICKETS

TO THE EDITOR:—Please discuss the use of vitamin D parenterally in the prophylaxis or treatment of rickets, especially when systematic oral administration is doubtful?

Joseph I. Waring, M.D., Charleston, S. C.

ANSWER.—The parenteral injection of vitamin D to infants has not found favor in this country mainly because of the easy availability of many oral preparations of vitamin D or vitamin D in combination with other fat and water-soluble preparations. Recent work in Germany has reawakened interest in parenteral administration of vitamins D₂ or D₃ (Berthold, H.: *Monatschr Kinderh.* 98:110-113, 1950; Roos, *ibid.* 98:457-462, 1950; Kenn, *ibid.* 98:479-481, 1950). Doses ranging from 125 units to 50,000 units of vitamin D₂ or D₃ were given intramuscularly to newborn infants or 4 to 6 week old infants. Greater prevention of rickets was obtained with two 12,500 unit doses given three months apart than with the single 25,000 unit injection. Smaller doses of crystalline D₃ were effective in some patients in hastening the correction of florid rickets. Toxic reaction to the dosages listed above were not encountered. No agreement can be established from the reports that a single injection or several injections once monthly will be certain protection against rickets in all infants. Craniotabes is not an infallible sign of rickets. Roentgenograms of long bones

are more definitive and should be obtained. Prophylactically the well-established principle of daily oral administration of vitamin D would seem to have greater merit as judged from the lack of rickets in this country.

ANTHRAX

TO THE EDITOR:—What is the most effective treatment for anthrax and is there any prophylactic serum worth giving?

Walter L. Twarog, M.D., Lowell, Mass.

ANSWER.—Good results have been reported with large doses of penicillin administered at four hour intervals for a period of about five days. It has also been stated that chlortetracycline (Aureomycin), oxytetracycline (Terramycin), and chloramphenicol (Chloromycetin) are equally effective and that the sulfonamides produce a good response. Formerly an antiserum was used, but it is now difficult if not impossible to obtain. The elimination of the disease in animals is the only sure method of preventing the infection in man. Active immunization is resorted to for animals but is not available for humans. Woolsorters' disease (pulmonary anthrax) may be prevented by adoption of sanitary measures for protection of the workers.

CORK DUST

TO THE EDITOR:—I would like information on the question of cork dust as an irritant in causing pneumoconiosis and also on any allergies associated with cork or cork dust. There are no chemicals involved in my case.

W. S. Nettrour, M.D., Pittsburgh, Pa.

ANSWER.—Cork dust is credited with the property of respiratory tract irritation, but perhaps is no more active than dust from ordinary woods in equal concentration and fineness. No significant pneumoconiosis is expectable. Some cork bottle stoppers are now made from sections of this substance glued together and then are ground down leading to dustiness. This glue, rather than the cork dust, could be the source of allergic disturbances. In many operations in which cork is manipulated, such as the manufacture of cork brick or linoleum, ancillary chemicals have led to distinct damage, including epitheliomas. However, the cork itself never has been implicated. The real danger attending cork dust in a workroom is that of dust explosions.

ABNORMAL BLOOD SUGAR AND DISABILITY INSURANCE

TO THE EDITOR:—An insurance company requested a glucose tolerance test when they noted the history of diabetes mellitus in my mother. A glucose tolerance test on repeated examination revealed an elevated broad diabetic type of curve beginning with a normal fasting blood sugar. I have never had sugar in the urine nor had an abnormal fasting sugar level in the urine nor an abnormal fasting blood sugar level. I was disqualified for disability insurance benefits on the basis of "an abnormal blood sugar." At age 42, with the family history of diabetes mellitus with retinopathy and foot ulcers in my mother and a broad glucose tolerance curve, what is my prognosis? Is any treatment other than weight control indicated?

M.D., Pennsylvania.

ANSWER.—The prognosis would probably be about that of an ordinary person, because knowledge of your mother's condition naturally would favor your living a sensible and cautious life. Even if you actually had diabetes at age 40, the prognosis would be for a life span three-fourths that of your average contemporaries. Control of body weight so that it approximates the standard for your age and height is the most essential protection. As for diet, limit the carbohydrate intake to 250 gm. daily and nearer 200 gm. if the dressed weight is less than 150 lb. (68 kg.). Every three months a test of the blood sugar an hour after the noon meal, together with a test for glycosuria, would be desirable.

ASCHHEIM-ZONDEK TEST

TO THE EDITOR:—In THE JOURNAL, Nov. 28, 1953, page 1229, an answer to a question states that "A positive reaction to the Aschheim-Zondek or other biological test does not always indicate the presence of a pregnancy, a hydatidiform mole or a chorionepithelioma." This is incorrect.

With the 24 hour rat pregnancy test of Frank and Berman (Am. J. Obst. & Gynec. 42:492, 1941; Berman, *ibid.* 64:440, 1952), it is impossible to get a positive result in any of the seven conditions other than pregnancy, hydatidiform mole, and chorionepithelioma outlined in the answer. The test is based on the presence of large amounts of chorionic gonadotropic hormone associated with pregnancy, hydatidiform mole, or chorionepithelioma. In the menopause (spontaneous or artificial), for instance more gonadotropin is excreted than in a normal menstruating woman. However, it is necessary to inject into animals the equivalent of 100 to 200 ml. of extracted urine to elicit a response in routine gonadotropin assays. In the Frank and Berman pregnancy test, a total of 10 ml. of urine (not extracted) is injected into a test animal. One can readily see, therefore, the impossibility of obtaining a positive result with urine from menopausal women, and so with the other conditions outlined. Urines should not be done for pregnancy testing when a patient is taking hormones (except thyroid) because of toxicity to animals. If a test is necessary while a patient is taking hormones, the test should be done with blood serum to obviate toxicity. No false positive or false negative results (e. g., when patient is receiving estrogens for threatened abortion) have been encountered. False positive results are being reported to physicians constantly. The physician should be alerted to the following reasons for these false positive results (and also the dearth of false negative results).

1. False positive results may be obtained if the laboratory performing the test is not following the proper technique. (A patient was referred to our laboratory recently for whom a negative pregnancy test result was issued. The physician who referred the patient called to advise that another laboratory doing the Frank and Berman pregnancy test had reported a positive result for the same patient. Both laboratories repeated the pregnancy test, again getting different results. In conversation with the director of the other laboratory, it was discovered that mature rats weighing 125 gm. had been used when the Frank and Berman pregnancy test specifies immature 50 gm. rats. The other laboratory was reporting on the mature ovaries of the rats rather than on the patient's specimen. This was a menopausal patient.)
2. Pregnancy tests with the male frog as the test animal give not only false negative results but also false positive ones. Every paper published on this test has reported this.
3. Obviously, carelessness in the laboratory in mixing up specimens will give misleading results.
4. Results of the "sink test" are not reliable.

The pregnancy test is used to diagnose pregnancy, the presence of retained fragments of placenta or chorionic tissue, hydatidiform mole, and chorionepithelioma in men as well as women. The pregnancy test will not predict abortion, will not indicate the progress of the pregnancy, will not indicate whether the fetus is dead or alive, will not establish an ectopic pregnancy, and will not reveal the ovulation time.

Certain precautions must be observed by the patient referred for a pregnancy test or the test may be valueless. The instructions to be given patients are as follows: 1. Take no medicaments, including hormones, neostigmine (prostigmine), antihistaminics, laxatives, sulfonamides, quinine, or ergot, for 96 hours prior to the test. 2. Drink no alcoholic beverages for 24 hours prior to test. 3. Save the first urine on arising plus any urine that may be obtained during the sleeping period and refrigerate the specimens immediately and until they are brought to the laboratory. 4. Bring a 2 oz. (60 cc.) specimen to the laboratory in the morning.

Berman Clinical Laboratory
134 W. 58th St., New York 19.

OTOSCLEROSIS

TO THE EDITOR:—I would like to comment on the answer to the query on page 101 of THE JOURNAL, Jan. 2, entitled "Otosclerosis." I object to the diagnosis being made without at least knowing the findings of a properly done air conduction and bone conduction audiogram. I also take exception to the fact that no suggestion was made regarding the possibility of having fenestration surgery done if adequate cochlear reserve is present, particularly in a person only 36 years old. May I conclude by saying I greatly enjoy your section on Queries and Minor Notes.

James W. McLaurin, M.D.
Reymond Bldg., Baton Rouge, La.

TO THE EDITOR:—In reply to a letter in THE JOURNAL, Jan. 2, 1954, regarding a patient with progressive loss of hearing and tinnitus, it was stated that this condition might have been otosclerosis. It was mentioned that any known therapy was useless, and a hearing aid was recommended if the deafness continued. If the case is one of pure conductive deafness wherein there is little or no acoustic nerve deterioration, and if the hearing falls below a practical level bilaterally, it should be mentioned that a fenestration operation can be performed with an excellent chance of restoring the patient's hearing to a serviceable level. The percentage of success in such a patient, who is classified as a class A candidate for this operation, is about 70% and class B 50%. Anyone with less chance of success should probably wear a hearing aid rather than undertake the fenestration operation.

James E. Coyle
573 Fisher Bldg., Detroit 2.

TO THE EDITOR:—On page 101, THE JOURNAL, Jan. 2, there is an answer to a query as to the proper treatment for progressive loss of hearing and tinnitus aurium of a year's duration. The answer given was so misleading that I think correction should be made. First of all, one cannot tell from the question whether this patient has otosclerosis, since an adequate hearing test is not reported. Secondly, if clinical otosclerosis is present, the answer failed to mention what is probably the most outstanding surgical procedure of the present century, namely, the fenestration operation for the restoration of hearing in persons with otosclerosis. Since this can correct hearing in 80% or more of suitable cases so that patients can return to normal useful lives without the use of a hearing aid, it would seem that such a possibility should be mentioned.

Charles A. Tucker, M.D.
Medical Bldg., Hartford 6, Conn.

TO THE EDITOR:—The answer to Dr. Daniel Burman's query on otosclerosis published in THE JOURNAL, Jan. 2, is inaccurate. In the first place, the diagnostic criteria for otosclerosis mentioned in the answer are erroneous and might cover any number of cases of nerve deafness. Otosclerosis is a conduction-type of hearing impairment with good bone perception and usually there is a normal eustachian tube, middle ear, and drum.

The statement that "any known therapy is useless" is untrue, and the experience of thousands of otologists and patients contradicts it. At the last meeting of the American Otological Society, Dr. Julius Lempert was given a medal of honor as the otologist who had contributed most to the present generation for his work on the fenestration operation. In patients with true otosclerosis and no marked nerve degeneration the fenestration operation is a great boon.

P. W. Snelling, M.D.
111 Pearl St., Hartford 3, Conn.

TO THE EDITOR:—We feel that a more accurate reply is indicated to the question on otosclerosis in Queries and Minor Notes in THE JOURNAL, Jan. 2, and wish to add our comment to the many we are sure you will receive regarding this reply. Certainly the excellent results obtained by the fenestration operation warrant its consideration.

GALLBLADDER DISEASE IN ADOLESCENTS AND YOUNG ADULTS

George D. J. Griffin, M.D.

and

Lucian A. Smith, M.D., Rochester, Minn.

Since the beginning of the era of modern medicine, students have been taught that disease of the gallbladder is an affliction of the middle or later years of life. All physicians have heard variations of the "fair, fat female of 40." It is well to indoctrinate medical students with such easily remembered maxims, but this particular aphorism is better forgotten, for it can lead to serious error. As an example, it was not unusual to read in the histories of the cases of gallbladder disease in the adolescent and young adult that are reported, "Age of patient against the diagnosis of cholecystitis, but . . ."

An effort was made to estimate as closely as possible the occurrence of disease of the gallbladder in adolescents and young adults seen in a community the size of Rochester, Minn., which has a population of approximately 30,000.

METHODS

The records of all permanent residents of Rochester who had disease of the gallbladder and in whom the diagnoses were made at the Mayo Clinic for the first time during the years 1948 and 1949 were surveyed. The resulting estimate suffers in that all patients who had this disease in Rochester during those years were not seen at the clinic. Local physicians undoubtedly saw many such patients during this period. However, these records probably do include all instances in which cholecystectomy was performed on residents during those years.

To be certain that the patients in this study actually had disease of the gallbladder, only those patients were included in whom gallstones were evident on roentgenographic study or in whom pathological examination after operation proved the presence of cholecystitis. This undoubtedly excluded many patients in whom medical management was used, such as those in whom nonfunctioning gallbladders were present without evidence of formation of stones after repeated roentgenograms and those in whom typical biliary colics had occurred but who had not undergone gallbladder roentgenography or operation. In the last group were a great many adoles-

cents and young adults who will in time have proved cholecystitis by the aforementioned standards. Also excluded were patients who had metastatic carcinoma of the gallbladder and complications of diseased gallbladders, such as postcholecystectomy syndromes of choledocholithiasis, stricture, or spasm of the common bile duct. It should be noted that this report includes no patients who had "silent gallstones" who were less than 35 years of age. Such patients undoubtedly exist yet remain undetected because of the absence of other diseases that would bring them to medical investigation, thus allowing incidental disclosure of the gallstones.

The remaining patients were divided into four categories: (1) those in whom cholecystectomies were performed; (2) those who were under medical management and who were currently symptomatic; (3) those who were currently asymptomatic; and (4) those who had primary carcinoma of the gallbladder.

For interest, a survey was made of the records of all patients 25 years of age or less, resident or nonresident, who were operated on at the clinic during the years 1948 and 1949 for diseases of the gallbladder. It was thought that by expanding the number of patients in this age group and limiting the patients considered to only those who had disease of the gallbladder proved by operation, we might obtain information concerning the frequency of congenital hemolytic icterus as a cause of disease of the gallbladder in young persons.

RESULTS

This study included 245 patients, of whom 154 had been operated on for cholecystitis, 65 were currently symptomatic and under medical management, 21 were asymptomatic, and 5 had carcinoma of the gallbladder. Analysis of the ages of these patients (see table) showed that cholecystic disease occurred in all age groups beginning with 15 years, a fact at variance with the common concept of the age incidence. It must be pointed out again, however, that this estimate suffers by the absence of many nonsurgical patients in all age groups.

Fellow in Surgery, Mayo Foundation (Dr. Griffin), and Division of Medicine, Mayo Clinic and Mayo Foundation (Dr. Smith). The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

The analysis shows that 3.3% of the patients were 20 years of age or less, 2.9% were between 21 and 25 years of age, and 8.2% were between the ages of 26 and 30. Thus, 6.2% were 25 years of age or less, and 14.4% were 30 years of age or less. In this latter combined group, the mean age was 24 years. The mean age of these patients at the onset of symptoms of cholecystic disease was 18 years; thus disease of the gallbladder begins at an age that is even less than our figures would imply.

The influence of the sex of the patient in cholecystitis is undeniable. Of the 240 patients who had noncarcinomatous cholecystitic disease, only 35 (14.6%) were males. The sex incidence is not wholly dependent on pregnancy, for of the 15 resident patients who were 25 years of age or less, only 4 had been pregnant.

While it is known that cholecystic disease is a complication in more than 50% of patients who have congenital hemolytic icterus, it does not follow necessarily that a majority of adolescents and young adults who have cholecystitis also have congenital hemolytic icterus. Cholecystectomies were done in 1948 and 1949 on 40 resident and nonresident patients who were 25 years of age or less; 3 were males. Two of these 40 patients pre-

was done. Pathological examination disclosed chronic ulcerative cholecystitis with multiple (seven) stones, each 2 mm. in diameter.

CASE 2.—The patient was a 15-year-old girl who had had 10 attacks of right subcostal pain with nausea and vomiting, but little abdominal tenderness. During the last two attacks, pain had extended to the back. Her mother had noted gallbladder colic at the age of 17 and had undergone cholecystectomy at the age of 28. Roentgenograms showed a functioning gallbladder with stones. Operation was postponed because the patient was obese.

CASE 3.—The patient was a 25-year-old woman who, since the age of 6, had experienced many attacks of upper mid-epigastric pain. The pain was of sudden onset and was severe and colicky in nature; it often extended to the right scapula and was followed by nausea and vomiting. She recalled several such attacks during her years at grammar school, two during high school, and four in the previous four years. No history of jaundice was obtained. Each attack had required hypodermic injections for relief of pain. Residual pain in the epigastrium usually lingered for three days. Fever and leukocytosis had been present during the recent attacks. Gallstones had been found during roentgenography four years prior to registration at the clinic. Her brother had disease of the gallbladder. Roentgenograms of the gallbladder taken during examination at the clinic disclosed no abnormalities. The patient refused operation.

Age Incidence in 245 Cases of Gallbladder Disease

Diagnosis	Age, Yr.													Total
	16-20	21-25	26-30	31-35	36-40	41-45	46-50	51-55	56-60	61-65	66-70	71-75	76 or More

Cholecystitis; medical treatment; symptomatic....	2	3	2	3	2	3	5	8	10	11	7	4	5	65
Cholecystitis; asymptomatic.....	..	..	..	..	2	2	3	3	2	4	2	3	1	21
Carcinoma of gallbladder.....	..	..	..	..	..	..	..	..	1	1	2	1	..	5
Total	8	7	20	19	18	20	25	32	26	29	21	10	10	245
Percentage	3.3	2.9	8.2	7.7	7.3	8.2	10.2	13.1	10.6	11.8	8.5	4.1	4.1	100.0

* One patient was 14 years of age.

sented conclusive clinical, laboratory and pathological evidence of hemolytic disease in addition to cholecystitis; 2 others had questionable evidence of hemolytic icterus. In one of these last two patients, the spleen was removed; it was proved later that the patient had Hodgkin's disease of the bones. Thus, neither congenital hemolytic icterus nor pregnancy can be called a prime cause of cholecystitis in adolescents or young adults.

The following cases are illustrative of histories that were encountered frequently during this study. We have been impressed by the occurrence of a family history of disease of the gallbladder in a majority of those cases of cholecystitis that we have seen. When such a familial background was not reported in a given case in this study, it usually represented failure to search for this valuable diagnostic aid. The report of Dixon and Owen¹ supports this opinion.

REPORT OF CASES

CASE 1.—The patient was a 14-year-old girl. One year prior to registration at the clinic, pain appeared in the right upper quadrant; this pain radiated to the right scapula and was associated with nausea, vomiting, and tenderness in the right upper quadrant of the abdomen. Three such attacks occurred during the year. No family history was recorded. Roentgenograms showed a nonfunctioning gallbladder. Cholecystectomy

CASE 4.—The patient was a 27-year-old woman. Between 11 and 14 years of age, the patient had noted dyspepsia after eating fried or fatty foods; this was associated occasionally with mild right subcostal nonradiating pain. She had experienced no difficulty again until the age of 19, at her first pregnancy. At this time and during each of six pregnancies thereafter, she had had one or two mild to severe attacks of typical gallbladder colic. During the last episode, which was severe, she had been jaundiced for the first time. No family history was recorded. Cholecystectomy was done. Pathological examination disclosed subacute and chronic cholecystitis with multiple stones; a stone was present in the common bile duct.

This case illustrates cholecystitis present before but accentuated by pregnancy.

CASE 5.—The patient was a 40-year-old woman for whom a gallbladder diet had been prescribed at the age of 20 because of attacks of pain in the upper part of the abdomen and gaseous distention with severe malaise; these symptoms were accompanied by a desire to vomit or belch but an inability to do either. Since then, she had experienced three to four attacks a year after meals. The distress was described as "discomfort which sits below the breastbone like a fist." The duration of an attack was one to two hours. Through the years she had had dyspepsia after eating greasy foods, cabbage, or pork. The last acute episode had occurred after eating cabbage. She had been pregnant twice, at 19 and 21 years of age. Roentgenograms taken two years before registration showed nothing abnormal. Roentgenograms taken at the clinic revealed a functioning gallbladder with stones. Her mother had "died of gallstones." One sister and a brother had had cholecystectomies. Operation was refused by the patient.

1. Dixon, C. F., and Owen, H. W.: Cholelithiasis: Familial Predisposition, *S. Clin. North America* 32: 1177-1180 (Aug.) 1952.

This case demonstrates a 20 year history of probable cholecystic disease beginning in early adult years with distress that was moderate to severe on several occasions each year; in spite of this, the gallbladder was demonstrated roentgenographically to be functional at the age of 38.

CASE 6.—The patient was a 29-year-old woman who had had severe epigastric colic at the age of 16; this occurred three days post partum. The attack came after a meal of pork and beans. Later she had been told that she had disease of the gallbladder. She had noted distress throughout the years after eating cabbage, onions, and uncooked apples. Frequent colics occurred, requiring hypodermic injections for relief of pain. A nonfunctioning gallbladder had been diagnosed by roentgenograms one year before registration at the clinic. Since then she had experienced numerous colics, not being free of symptoms for more than a month at a time. She had had almost continual colic during the six weeks before coming to the clinic. Diffuse soreness in the right upper abdominal quadrant had been present; this was referred to the right subscapular region when most severe. Some nausea and vomiting and questionable chills but no jaundice or fever had been noted. Her paternal grandmother had had disease of the gallbladder.

Examination revealed a palpable gallbladder extending down to the level of the anterior superior iliac spine. Cholecystectomy was done. Pathological examination disclosed subacute and chronic cholecystitis with multiple stones ranging up to 2 cm. in diameter; hydrops of the gallbladder was present.

This patient had refused operation for 13 years because of fear.

CASE 7.—The patient was a 56-year-old woman. From the age of 17 and until the age of 30, she had experienced numerous attacks of severe epigastric pain that extended around the right subcostal margin to beneath the right scapula; the attacks lasted 10 to 20 minutes and occurred three to four times each month. From the age of 30 until 7 months before examination at the clinic, she had continued to have these episodes but at less frequent intervals. During the 7 months prior to registration, attacks occurred every 10 to 14 days. She had been extremely intolerant throughout the years to fried or greasy foods. Often she had noted dyspepsia and belching. She had been pregnant five times, first at the age of 21. Her mother, two sisters, and one daughter had had cholecystic disease. There was no history of congenital hemolytic icterus. Cholecystectomy was done. Pathological examination disclosed chronic cholecystitis with multiple stones.

This case demonstrates the human capacity to tolerate severe and limiting illnesses. The patient had a 39 year history of intermittent severe distress.

COMMENT

This study emphasizes the fact that cholecystitis occurs in adolescents and young adults. The value of early diagnosis and early surgical extirpation of the calculous gallbladder has been stressed sufficiently in the past. Too often age, infection, or formation of stones in the biliary tree and hepatic damage have increased needlessly the surgical risk to the patient.

The impression was obtained in the practice of one of us (L. A. S.) that the commonly used dictum of the "fair, fat female of 40" can lead to serious error. This impression appears to be confirmed by this study. Among the cases of disease of the gallbladder in adolescents and young adults just reported, such initial diagnoses were made as abdominal migraine, appendicitis (with not uncommonly an appendectomy), Meckel's diverticulitis,

duodenal ulcer, hepatitis, pyelitis of pregnancy, nephritis, and functional abdominal pain. While such conditions occasionally can simulate cholecystitis and vice versa, it was clear in many instances that the diagnostician considered that the possibility of cholecystitis occurring in such young patients was exceedingly remote.

The concept of the "typical" or "classical" has its place in teaching the art of medicine. Dictums such as the one under attack are honest efforts to simplify learning in a difficult field. A majority of patients who have disease of the gallbladder are more than 40 years of age. But when nearly a third of patients are less than this typical age and when as many patients who have this disease are between the ages of 26 and 30 as are between the ages of 41 and 45, it is questionable whether this particular maxim has any real teaching value. Furthermore, when experienced physicians consider excluding the possibility of this common disease because the patient does not fit a pattern, it suggests that the pattern is too widely advertised and too rigidly considered. Therefore, this concept would be better forgotten.

SUMMARY

An effort was made to estimate as closely as possible the incidence of disease of the gallbladder in adolescents and young adults in a community the size of Rochester, Minn. A study was conducted of the records in 245 cases of cholecystic disease among permanent residents of Rochester in whom the diagnoses were made at the Mayo Clinic during the years 1948 and 1949. In addition, records were studied in 40 cases representing all patients 25 years of age or less on whom cholecystectomies were performed in 1948 and 1949. Neither pregnancy nor congenital hemolytic icterus appears to play a large part in the production of cholecystic disease in adolescents and young adults. It is suggested that the dictum "fair, fat female of 40" as a concept of the typical patient who has disease of the gallbladder be abandoned, because it can lead to serious error.

Appendicitis in Babies and the Aged.—Appendicitis occurring at the extremes of life may easily mislead us. A baby does not often get appendicitis, but when he does he cannot tell us much about it. He is sick and he yells, but all babies do that. The danger is that acute appendicitis in a baby very quickly goes on to general peritonitis, and general peritonitis in a baby is fatal. We can safeguard ourselves by making it an invariable rule never to leave our examination of a child complaining of abdominal pain without examining the right iliac fossa. Old people again are not very likely to suffer from acute appendicitis, but when they do the attack may be latent. . . . When they get colic and vomiting they have often had it before; they take a dose of salts or soda-bicarb and put a hot bottle on their tummies. When they feel as if they have a temperature they take a couple of aspirins. They are seen by the doctor when they have a large localized abscess. A fairly common story is that of an old man whose only complaint is of the frequent passage of stools containing little but blood and mucus. This story at once suggests a carcinoma of the rectum or pelvi-rectal junction, except that he has a temperature, has been ill for a fortnight only and has not lost weight. On putting a finger in the rectum, in place of the growth we expect, we find the doughy tender mass of a pelvic abscess bulging the anterior wall.—H. Ogilvie, M.D., *Misleading Cases, Medical World*, November, 1953.

SURGICAL ASPECTS OF CHOLEDOCHOLITHIASIS

John M. Waugh, M.D., Edward V. Johnston, M.D.

and

James C. Cain, M.D., Rochester, Minn.

The problem of common duct stones has been discussed frequently in the past decade. That continued emphasis and discussion are advisable is suggested by the history of previous operation on the biliary tract in 27% of our patients who had choledocholithiasis. Other authors have noted a similar incidence of previous, unsuccessful operations in patients with common duct stones.¹

A group of 175 consecutive cases in which common duct stones were removed at operation by one of us (J. M. W.) during the period from 1940 to July, 1950, have been reviewed. The only cases discarded from the series were those in which choledocholithiasis was associated with tumors and strictures of the common duct or acute pancreatitis and the latter conditions were the primary consideration, clinically and at operation. Although such a study does not provide data on the incidence of choledocholithiasis in patients undergoing cholecystectomy, the incidence has ranged from 10 to 16% at the Mayo Clinic in the past few years.²

SYMPTOMATOLOGY

The sex ratio was somewhat unusual, with 108 women and 67 men, a ratio of only 1.6 to 1.0. The ages of the patients ranged from 25 to 80 years and averaged 55.6 years.

Pain.—Typical biliary colic, severe enough to necessitate the administration of hypodermic injections for relief, was present in 125 patients (71.4%). Pain that was atypical in location but severe enough to require hypodermic medication (6 patients) and typical colicky pains of only moderate severity (7 patients) might well be included in the so-called typical biliary colic group because of the recognized variability of biliary tract pain (total

incidence, 79%). In the 37 patients remaining, the pain was classified as atypical in location and occurrence in 21, and was essentially absent in 16 patients (9%).

A history of very frequent episodes of colic was a notable feature in very few patients of this series. Certain authors have stressed the importance of episodes occurring at intervals of 14 days or less as evidence of the presence of stones in the common duct.³

Jaundice.—A clinical diagnosis of jaundice was made on admission in 86 cases, and in 36 of this group there was also a history of previous episodes of jaundice. A previous history of jaundice was noted for an additional 28 patients. A total of 114 patients, or 65% of the entire series, thus gave a history or clinical evidence of jaundice. Thirty-five per cent had never been aware of any jaundice.

The inadequacy of jaundice alone as an indication of the presence of common duct stones in cholelithiasis patients has been noted by many authors. The incidence of jaundice with choledocholithiasis has varied from 53 to 76% in previous studies.⁴ Jaundice has greater significance when accompanied by severe pain and intermittent acholic stools⁵ than when not so accompanied, and Buxton and Burk have stressed the importance of recent and frequent episodes of jaundice.^{4a}

Conversely, the absence of jaundice is no guarantee of the absence of common duct stones. Thirty-five per cent of the patients in this series had no jaundice, similar figures from the literature ranging from 24 to 47%.

Nausea and Vomiting.—Symptoms of nausea and vomiting occurred in 111 patients (74% of the 150 records in which their presence or absence was specifically noted). Nausea alone was noted in 19 instances, while no nausea or vomiting had occurred in 20 (13%) of the patients.

Chills and Fever and Acholic Stools.—Sixty-four patients gave a history of chills and fever. Fever alone was reported in 18, and chills without positive evidence of fever in an additional 3 patients. A definite history of very light or clay-colored stools was obtained in only 35% of the cases.

ROENTGENOGRAPHIC FINDINGS

Table 1 lists the results of the roentgenographic studies carried out on this group of patients. In interpreting the 12 simple roentgenograms of the abdomen in which calculi were visualized, the roentgenologist suggested that the stones were located in the common duct in 5 instances.

Cholecystograms were not ordered in 85 cases, in 49 because of the presence of jaundice too severe to expect an accurate roentgenogram and in 29 because of previous cholecystectomy. In seven patients the test was not carried out because of the presence of biliary fistulas or other complicating factors. The cholecysto-

grams were helpful in diagnosing the presence of cholecystic disease in 89% of the 90 cases in which they were indicated.

PREVIOUS BILIARY SURGICAL PROCEDURES

Forty-seven patients (27%) had undergone previous surgical procedures on the biliary tract or had had previous exploration for complaints that eventually proved to be of biliary causation. Only three of these earlier procedures had been done at the Mayo Clinic, two of them having been cholecystostomies for very acute processes.

Sixteen patients had had more than one biliary procedure, one patient having undergone four operations previously. Davidson and associates reported a 39% incidence of previous biliary tract operations in a series of patients found to have stones in the common duct.^{1a}

Cholecystectomy had been done in 29 patients. Only four of these patients gave a definite history of choledochotomy at the first operation, while four additional patients had common duct explorations as secondary procedures due to persistence or recurrence of symptoms.

Cholecystostomy had been the initial surgical procedure in 20 patients. Six of the 20 had undergone additional operations on the biliary tract because of recurrent symptoms, one cholecystectomy alone, and two cholecystectomy plus choledochotomy.

Choledochotomy alone had been carried out in one additional case. Thus, among the 47 choledocholithiasis patients previously operated on, a total of only 11 had a definite history of exploration of the common duct. More significant is the observation that, of the 16 patients who had undergone multiple biliary surgical procedures, only 6 patients (38%) were known to have undergone exploration of the common duct.

Although these figures on choledochotomy are based on the patient's history alone in certain instances, they serve to point out the frequency of this rather obvious indication for choledochotomy, the persistence or recurrence of definite symptoms such as biliary colic, jaundice, chills and fever, or prolonged drainage from the incision following previous biliary operative procedures.

The 11 patients in whom the common duct had been explored previously thus represent the problem of overlooked or re-formed stones in the common duct. The symptoms are of interest in eight of these cases in which no modifying circumstances were present on admission (such as the presence of a T-tube or operative choledochoduodenostomy). The onset of recurrent symptoms was within an average period of six and a half months following operation, and in all cases within two years. In four cases the symptoms recurred within a month following operation, and in one case each the onset was 4, 7, 12, and 24 months after operation. Severe biliary colic was noted in only three cases; jaundice had been present in six patients, nausea and vomiting in seven, and chills and fever in five patients.

A history of prolonged drainage of bile from the incision postoperatively was elicited in 15, or approximately one-third, of the 47 patients who had undergone previous exploration. Although the importance of this finding has been stressed in the diagnosis of strictures of the common duct, few authors have recorded its inci-

dence in those choledocholithiasis patients in whom any part of the extrahepatic biliary tract has been opened and in whom stones remain in the common duct. That an external biliary fistula will often heal within three to four weeks even in the presence of residual stones in the common duct has been pointed out by Hicken and associates.⁶ Before discussing further the indications for exploration of the common duct, let us briefly review the gallbladder and associated pathological findings that occur in such a series of patients with choledocholithiasis.

ASSOCIATED PATHOLOGICAL FINDINGS
